

# TOPCAT - Tool for Operations on Catalogues And Tables

## Version 2.1

Starlink User Note 253

Mark Taylor

7 April 2006

\$Id: sun253.xml,v 1.115 2006/04/07 11:29:16 mbt Exp \$

### Abstract

TOPCAT is an interactive graphical viewer and editor for tabular data. It has been designed for use with astronomical tables such as object catalogues, but is not restricted to astronomical applications. It understands a number of different astronomically important formats, and more formats can be added. It is designed to cope well with large tables; a million rows by a hundred columns should not present a problem even with modest memory and CPU resources.

It offers a variety of ways to view and analyse the data, including a browser for the cell data themselves, viewers for information about table and column metadata, tools for joining table using flexible matching algorithms, and visualisation facilities including histograms, 2- and 3-dimensional scatter plots, and density maps. Using a powerful and extensible Java-based

expression language new columns can be defined and row subsets selected for separate analysis. Selecting a row can be configured to trigger an action, for instance displaying an image of the catalogue object in an external viewer. Table data and metadata can be edited and the resulting modified table can be written out in a wide range of output formats.

TOPCAT is written in pure Java and is available under the GNU General Public Licence. Its underlying table processing facilities are provided by STIL, the Starlink Tables Infrastructure Library.

## 1 Introduction

TOPCAT is an interactive graphical program which can examine, analyse, combine, edit and write out tables. A table is, roughly, something with columns and rows; each column contains objects of the same type (for instance floating point numbers) and each row has an entry for each of the columns (though some entries might be blank). A common astronomical example of a table is an object catalogue.

TOPCAT can read in tables in a number of formats from various sources, allow you to inspect and manipulate them in various ways, and if you have edited them optionally write them out in the modified state for later use, again in a variety of formats. Here is a summary of its main capabilities:

- View/edit table data in a scrollable browser
- View/edit table metadata (parameters)
- View/edit column metadata (column names, units, UCDs...)
- Re-order and hide/reveal columns
- Insert 'synthetic' columns defined by algebraic expression
- Sort rows on the values in a given column
- Define row subsets in various ways, including algebraically and graphically
- Plot columns against each other in 1, 2 and 3 dimensions, distinguishing different subsets
- Calculate statistics on each column for some or all rows
- Trigger a configurable action (e.g. object image display) when a column is selected
- Perform flexible matching of rows in the same or different tables
- Concatenate the rows of existing tables to create new ones
- Acquire tables from web services, external filestores or other customisable sources
- Write modified tables out in original or different format

The general idea of the program is quite straightforward. At any time, it has a list of tables it knows about - these are displayed in the Control Window which is the first thing you see when you start up the program. You can add to the list by loading tables in, or by some actions which create new tables from the existing ones. When you select a table in the list by clicking on it, you can see general information about it in the control window, and you can also open more specialised view windows which allow you to inspect it in more detail or edit it. Some of the actions you can take, such as changing the current Sort Order, Row Subset or Column Set change the Apparent Table (Section 3), which is a view of the table used for things such as saving it and performing row matches. Changes that you make do not directly modify the tables on disk (or wherever they came from), but if you want to save the changes you have made, you can write the modified table(s) to a new location.

The main body of this document explains these ideas and capabilities in more detail, and Appendix A gives a full description of all the windows which form the application. While the program is running, this document is available via the online help system - clicking the **Help** () toolbar

button in any window will pop up a help browser open at the page which describes that window. This document is heavily hyperlinked, so you may find it easier to read in its HTML form than on paper.

Recent news about the program can be found on the TOPCAT web page (<http://www.starlink.ac.uk/topcat/>). It was initially developed within the now-terminated Starlink project. The underlying table handling facilities are supplied by the Starlink Tables Infrastructure Library STIL (<http://www.starlink.ac.uk/stil/>), which is documented more fully in SUN/252. The software is written in pure Java, and should run on any J2SE 1.4 or 1.5 platform. This makes it highly portable, since it can run on any machine which has a suitable Java installation, which is available for MS Windows, Mac OS X and most flavours of Unix amongst others. Some of the

external viewer applications it talks to rely on non-Java code however so one or two facilities, such as displaying spectra, may be absent in some cases. TOPCAT is available under the terms of the GNU General Public License.

## 2 Quick Start Guide

This manual aims to give detailed tutorial and reference documentation on most aspects of TOPCAT's capabilities, and reading it is an excellent way to learn about the program. However, it's quite a fat document, and if you feel you've got better things to do with your time than read it all, you should be able to do most things by playing around with the software and dipping into the manual (or equivalently the online help) when you can't see how to do something or the program isn't behaving as expected. This section provides a short introduction for the impatient, explaining how to get started.

To start the program, you will probably type `topcat` or something like `java -jar topcat-lite.jar` (see Section 9 for more detail). To view a table that you have on disk, you can either give its name on the command line or load it using the **Load** button from the GUI. FITS and VOTable files are recognised automatically; if your data is in another format such as ASCII (see Section 4.1) you need to tell the program (e.g. `-f ascii` on the command line). If you just want to try the program out, `topcat -demo` will start with a couple of small tables for demonstration purposes.

The first thing that you see is the Control Window (Appendix A.2). This has a list of the loaded table(s) on the left. If one of these is highlighted by clicking on it, information about it will be shown on the right; some of this (table name, sort order) you can change here. Along the top is a toolbar with a number of buttons, most of which open up new windows. These fall into a few groups:

Load/save etc.

Display various aspects of information about the table's data and metadata.

Open plotting/visualisation windows of various kinds.

Join tables in various ways, including spatial crossmatching

Help and information

The **Help** () button appears in most windows - if you click it a help browser will be displayed

showing an appropriate part of this manual. As well as the tool bar there are a number of menus along the top - most of the options just repeat those appearing on the toolbar, but a few less common ones may be available as well. All the windows follow roughly this pattern. For some of the toolbar buttons you can probably guess what they do from their icons, for others probably not - to find out you can hover with the mouse to see the tooltip, look in the menus, or read the manual, or just push it and see.

Some of the windows allow you to make changes of various sorts to the tables, such as performing sorts, selecting rows, modifying data or metadata. None of these affect the table on disk (or database, or wherever), but if you subsequently save the table the changes will be reflected in the table that you save.

An notable point to bear in mind concerns memory. TOPCAT is fairly efficient in use of memory, but in some cases when dealing with large tables you might see an `OutOfMemoryError`. It is usually possible to work round this by using either or both of the `-disk` or `-xmx NNN M` flags on startup - see Section 9.2.2.

Finally, if you have queries, comments or requests about the software, and they don't appear to be addressed in the manual, consult the TOPCAT web page and by all means contact the author - user feedback is always welcome.

### 3 Apparent Table

The **Apparent Table** is a particular view of a table which can be influenced by some of the viewing controls.

When you load a table into TOPCAT it has a number of characteristics like the number of columns and rows it contains, the order of the rows that make up the data, the data and metadata themselves, and so on. While manipulating it you can modify the way that the table appears to the program, by changing or adding data or metadata, or changing the order or selection of columns or rows that are visible. For each table its "apparent table" is a table which corresponds to the current state of the table according to the changes that you have made.

In detail, the apparent table consists of the table as it was originally imported into the program plus any of the following changes that you have made:

- Selection of rows changed by changing the current Row Subset (Section 3.1)
- Changes to the current Row Order (Section 3.2) caused by doing a sort
- Changes to the current Column Set (Section 3.3) caused by adding, hiding or moving columns
- Changes to cell data by editing cells in the Data window
- Changes to table metadata by editing cells in the Parameter window
- Changes to column metadata by editing cells in the Columns window

The apparent table is used in the following contexts:

#### Data Window

The Data window always shows the rows and columns of the apparent table, so if you are in doubt about what form a table will get exported in, you can see what it looks like there.

#### Exports

When you save a table, or export it by dragging it off the Table List panel in the Control Window, or create a duplicate table, it is the apparent table which is copied. So for instance if you define a subset containing only the first ten rows of a table and then save it to a new table, or create a duplicate within TOPCAT using the **Duplicate Table** () toolbar button, the

resulting table will contain only those ten rows.

#### Joins

When you use the Match Window or Concatenation Window to construct a new table on the basis of one or more existing ones, the new table will be built on the basis of the apparent versions of the tables being operated on.

Some of the other table view windows are affected too, for instance the Columns window displays its columns in the order that they appear in the Apparent Table.

### 3.1 Row Subsets

An important feature of TOPCAT is the ability to define and use **Row Subsets**. A Row Subset is a selection of the rows within a whole table being viewed within the application, or equivalently a new table composed from some subset of its rows. You can define these and use them in several different ways; the usefulness comes from defining them in one context and using them in another. The Subset Window displays the currently defined Row Subsets and permits some operations on them.

At any time each table has a **current** row subset, and this affects the Apparent Table. You can always see what it is by looking at the "Row Subset" selector in the Control Window when that table is selected; by default it is one containing all the rows. You can change it by choosing from

this selector or as a result of some other actions.

Other contexts in which subsets can be used are picking a selection of rows from which to calculate in the Statistics Window and marking groups of rows to plot using different markers in the Plot Window.

### 3.1.1 Defining Subsets

You can define a Row Subset in one of the following ways:

#### Selecting rows in the browser

You can select a single row in the Data Window by clicking on it, or select a group of adjacent rows by dragging the mouse over them. You can add more rows to the selection by keeping the <Control> button pressed while you do it. Once you have a set of rows selected you can use the **Subset From Selected Rows** () or **Subset From Unselected Rows** () buttons to create a new subset based on the set of highlighted rows or their complement.

Combining this with sorting the rows in the table can be useful; if you do a Sort Up on a given column and then drag out the top few rows of the table you can easily create a subset consisting of the highest values of a given column.

#### Defining an algebraic expression

From the Subset Window using the **Add New Subset** () button will pop up the Algebraic

Subset Window which allows you to define a new subset using an algebraic expression based on the values of the cells in each row. The format of such expressions is described in Section 6.

#### Visible plotted points

In some of the graphics windows you can plot columns against each other, and subsequently zoom in and out using the mouse. If you zoom to display only some of the plotted points and then use the **New Subset From Visible** ( or ) button then a new subset will be created containing only rows represented by points in the field of view of the plot at the time.

#### Selected plotted points

For more control over which plotted points are to be included in a subset, you can use the **Draw Subset Region** () button in some of the the graphics windows. This allows you to trace out with the mouse a region or regions of any shape, creating a new subset containing only those rows represented by the points within those regions.

#### Boolean columns

Any column which has a boolean (true/false) type value can be used as a subset; rows in which it has a true value are in the subset and others are not. Any boolean column in a table is made available as a row subset with the same name when the table is imported.

In all these cases you will be asked to assign a name for the subset. As with column names, it is a good idea to follow a few rules for these names so that they can be used in algebraic expressions. They should be:

- Different from other subset and column names, even apart from upper/lower case distinctions
- In the form of a java identifier (starts with a letter, continues with alphanumerics including underscore, no spaces)
- Not too long

In the first two subset definition methods above, the **current** subset will be set immediately to the

newly created one.

### 3.2 Row Order

You can sort the rows of each table according to the values in a selected column. Normally you will want to sort on a numeric column, but other values may be sortable too, for instance a String column will sort alphabetically. Some kinds of columns (e.g. array ones) don't have any well-defined order, and it is not possible to select these for sorting on.

At any time, each table has a **current** row order, and this affects the Apparent Table. You can always see what it is by looking under the "Sort Order" item in the Control Window when that table is selected; by default it is "(none)", which means the rows have the same order as that of the table they were loaded in from. The little arrow () indicates whether the sense of the sort is up or down. You can change the sort order by selecting a column name from this control, and change the sense by clicking on the arrow. The sort order can also be changed by using menu items in the Columns Window or right-clicking popup menus in the Data Window.

Selecting a column to sort by calculates the new row order by performing a sort on the cell values there and then. If the table data change somehow (e.g. because you edit cells in the table) then it is possible for the sort order to become out of date.

The current row order affects the Apparent Table, and hence determines the order of rows in tables which are exported in any way (e.g. written out) from TOPCAT. You can always see the rows in their currently sorted order in the Data Window.

### 3.3 Column Set

When each table is imported it has a list of columns. Each column has header information which determines the kind of data which can fill the cells of that column as well as a name, and maybe some additional information like units and Unified Content Descriptor. All this information can be viewed, and in some cases modified, in the Columns Window.

During the lifetime of the table within TOPCAT, this list of columns can be changed by adding new columns, hiding (and perhaps subsequently revealing) existing columns, and changing their order. The current state of which columns are present and visible and what order they are in is collectively known as the **Column Set**, and affects the Apparent Table. The current Column Set is always reflected in the order in which columns are displayed in the Data Window and Statistics Window. The Columns Window shows all the known columns, including hidden ones, in Column Set order; whether they are currently visible is indicated by the (leftmost) "Visible" column.

You can affect the current Column Set in the following ways:

#### Hide/Reveal columns

In the Columns Window you can toggle columns between hidden and visible by clicking on their box in the **Visible** column. To make a group of columns hidden or visible at once, select the corresponding rows (drag the mouse over them to select a contiguous group; hold the Control button down to add more single rows or contiguous groups to the selection) and hit the **Hide Selected** () or **Reveal Selected** () button in the toolbar or menu. Note when

selecting rows, don't drag the mouse over the Visible column, do it somewhere in the middle of the table. The **Hide All** ( ) and **Reveal All** ( ) buttons set all columns in the table

invisible or visible - a useful convenience if you've got a very wide table.

You can also hide a column by right-clicking on it in the Data Window, which brings up a

popup menu - select the **Hide** option. To make it visible again you have to go to the Columns Window as above.

### Move Columns

In the Data Window you can move columns around by dragging the grey column header left or right to a new position (as usual in a JTable). This affects the Column Set, as you can see if you watch the Columns Window while you do it.

### Add Columns

You can use the **New Synthetic Column** () or **New Sky Coordinate Columns** () buttons in the Columns Window or the (right-click) popup menu in the Data Window to add new columns derived from existing ones.

### Replace a Column

If a column is selected in the Columns Window or from the Data Window popup menu you can use the **Replace Column with Synthetic** () button. This is similar to the **Add a**

**Synthetic Column** described in the previous item, but it pops up a new column dialogue with similar characteristics (name, units etc) to those of the column that's being replaced, and when completed it slots the new column in to the table hiding the old one.

### Add a Subset Column

If you have defined a Row Subset somehow and you want it to appear explicitly in the table (for instance so that when you write the table out the selection is saved) you can select that subset in the Subsets Window and use the **To Column** () button, which will add a new

boolean column to the table with the value **true** for rows part of that subset and **false** for the other rows.

## 4 Table Formats

TOPCAT supports a wide variety of tabular data formats. In most cases these are file formats for tables stored as single files on a disk or at the end of a URL, but there are other possibilities, for instance a table you have opened could be the result of an SQL query on a database.

Since you can load a table from one format and save it in a different one, TOPCAT can be used to convert a table from one format to another. If this is all you want to do however, you may find it more convenient to use the `tcopy` command line utility in the STILTS package.

The format handling is extensible, so new formats can be added fairly easily. All the table input/output is handled by STIL, the Starlink Tables Infrastructure Library; more detailed descriptions of the I/O capabilities can be found in its documentation (<http://www.starlink.ac.uk/stil/>).

The following subsections describe the available formats for reading and writing tables. The two operations are separate, so not all the supported input formats have matching output formats and vice versa.

### 4.1 Supported Input Formats

Loading tables into TOPCAT is done either from the command line when you start the program up or using the Load Table dialogue. For FITS and VOTable formats the file format can be detected automatically (note this is done by looking at the file content, it has nothing to do with filename extensions). For other formats though, for instance ASCII or Comma-Separated Values, you will have to specify the format that the file is in. In the Load Window, there is a selection box from which you can choose the format, and from the command line you use the `-f` flag - see Section 9 for details. You can always specify the format rather than using automatic detection if you prefer - this can be a good idea if a table appears to be failing to load in a surprising way, since it may give you a more detailed error message.

In either case, table locations may be given as filenames or as URLs, and any data compression (gzip, unix compress and bzip2) will be automatically detected and dealt with.

**Note:** in some earlier versions of TOPCAT, ASCII format tables could be detected automatically, so you could load them by typing something like `topcat table.txt`. In the current version, you have to signal that this is an ASCII table, for instance by typing `topcat -f ascii table.txt`.

The following sections describe the table formats which TOPCAT can read.

#### 4.1.1 FITS

FITS binary and ASCII table extensions can be read. Unless told otherwise, TOPCAT will display the first TABLE or BINTABLE extension in a given FITS file. If a later extension is required, this is indicated by giving the extension number after a '#' at the end of the table location. The first extension (first HDU after the primary HDU) is numbered 1. Thus in a compressed FITS table named `spec23.fits.gz` with one primary HDU and two BINTABLE extensions, you would view the first one using the name `spec23.fits.gz` or `spec23.fits.gz#1` and the second one using the name `spec23.fits.gz#2`. The suffix `#0` is never used for a legal FITS file, since the primary HDU cannot contain a table.

You can select which extension to use more conveniently than by specifying the HDU numbers if you use the Hierarchy Browser to load the table.

If the table has been written using TOPCAT's "fits-plus" output format (see Section 4.2.1) then the metadata will be read in from the primary HDU as well.

If the table is stored in a FITS binary table extension in a file on local disk in uncompressed form, then the table is 'mapped' into memory - this generally means fast loading and low memory use, even in the absence of TOPCAT's `-disk` flag (Section 9.1).

### 4.1.2 VOTable

VOTable is an XML-based format for tabular data endorsed by the International Virtual Observatory Alliance; while the tabular data which can be encoded is by design close to what FITS allows, it provides for much richer encoding of structure and metadata. TOPCAT is believed to read any table which conforms to the VOTable 1.0 or VOTable 1.1 specification (<http://www.ivoa.net/Documents/latest/VOT.html>). This includes tables in which the cell data are included in-line as XML elements (VOTable/TABLEDATA format), or included/referenced as a FITS table (VOTable/FITS) or included/referenced as a raw binary stream (VOTable/BINARY). TOPCAT does not attempt to be fussy about input VOTable documents, and it will have a good go at reading VOTables which violate the standards in various ways.

VOTable documents can have a complicated hierarchical structure, and may contain more than one actual table. Unless told otherwise, TOPCAT will load the first table it finds in the document, so in the (common) case that the document holds exactly one table, giving the filename will load that sole table. To display a table other than the first, you must indicate the zero-based index of the TABLE element in a breadth-first search after a '#' character at the end of the table specification. Here is an example VOTable document:

```
<VOTABLE>
  <RESOURCE>
    <TABLE name="Star Catalogue"> ... </TABLE>
    <TABLE name="Galaxy Catalogue"> ... </TABLE>
  </RESOURCE>
</VOTABLE>
```

If this is available in a file named "cats.xml" then open the Star Catalogue using the name "cats.xml" or "cats.xml#0", and the Galaxy Catalogue using the name "cats.xml#1".

### 4.1.3 ASCII

In many cases tables are stored in some sort of unstructured plain text format, with cells separated by spaces or some other delimiters. There is a wide variety of such formats depending on what delimiters are used, how columns are identified, whether blank values are permitted and so on. It is impossible to cope with them all, but TOPCAT attempts to make a good guess about how to interpret a given ASCII file as a table, which in many cases is successful. In particular, if you just have columns of numbers separated by something that looks like spaces, you should be just fine.

Here are the detailed rules for how the ASCII-format tables are interpreted:

- Bytes in the file are interpreted as ASCII characters
- Each table row is represented by a single line of text
- Lines are terminated by one or more contiguous line termination characters: line feed (0x0A) or carriage return (0x0D)
- Within a line, fields are separated by one or more whitespace characters: space (" ") or tab (0x09)
- A field is either an unquoted sequence of non-whitespace characters, or a sequence of non-newline characters between matching single (') or double (") quote characters - spaces are therefore allowed in quoted fields
- Within a quoted field, whitespace characters are permitted and are treated literally
- Within a quoted field, any character preceded by a backslash character ("\") is treated literally.

This allows quote characters to appear within a quoted string.

- An empty quoted string (two adjacent quotes) or the string "null" (unquoted) represents the null value
- All data lines must contain the same number of fields (this is the number of columns in the table)
- The data type of a column is guessed according to the fields that appear in the table. If all the fields in one column can be parsed as integers (or null values), then that column will turn into an integer-type column. The types that are tried, in order of preference, are: Boolean, Short Integer, Long, Float, Double, String
- Empty lines are ignored
- Anything after a hash character "#" (except one in a quoted string) on a line is ignored as far as table data goes; any line which starts with a "!" is also ignored. However, lines which start with a "#" or "!" at the start of the table (before any data lines) will be interpreted as metadata as follows:
  - The last "#/!"-starting line before the first data line may contain the column names. If it has the same number of fields as there are columns in the table, each field will be taken to be the title of the corresponding column. Otherwise, it will be taken as a normal comment line.
  - Any comment lines before the first data line not covered by the above will be concatenated to form the "description" parameter of the table.

If the list of rules above looks frightening, don't worry, in many cases it ought to make sense of a table without you having to read the small print. Here is an example of a suitable ASCII-format table:

```
#
# Here is a list of some animals.
#
# RECNO  SPECIES      NAME          LEGS  HEIGHT/m
# 1      pig          "Pigling Bland"  4    0.8
# 2      cow          Daisy          4     2
# 3      goldfish     Dobbin         " "   0.05
# 4      ant           " "           6    0.001
# 5      ant           " "           6    0.001
# 6      ant           ' '           6    0.001
# 7      "queen ant"  'Ma\'am'      6    2e-3
# 8      human        "Mark"        2    1.8
```

In this case it will identify the following columns:

Name	Type
----	----
RECNO	Short
SPECIES	String
NAME	String
LEGS	Short
HEIGHT/m	Float

It will also use the text "Here is a list of some animals" as the Description parameter of the table. Without any of the comment lines, it would still interpret the table, but the columns would be given the names col1..col5.

If you understand the format of your files but they don't exactly match the criteria above, the best thing is probably to write a simple free-standing program or script which will convert them into the format described here. You may find Perl or awk suitable languages for this sort of thing.

This format is not detected automatically - you must specify that you wish to load a table in `ascii` format.

#### 4.1.4 IPAC

CalTech's Infrared Processing and Analysis Center use a text-based format for storage of tabular data, defined at [http://irsa.ipac.caltech.edu/applications/DDGEN/Doc/ipac\\_tbl.html](http://irsa.ipac.caltech.edu/applications/DDGEN/Doc/ipac_tbl.html). Tables can store column name, type, units and null values, as well as table parameters. They typically have a filename extension ".tbl" and are used for Spitzer data amongst other things. An example looks like this:

```

\title='Animals'
\ This is a table with some animals in it.
|   RECNO   | SPECIES | NAME | LEGS | HEIGHT |
|   char   |   char  | char |  int  | double |
|           |         |      |       | m       |
|           |         |      |       |         |
|     1    |   pig   | Pigling Bland | 4 | 0.8 |
|     2    |   cow   | Daisy | 4 | 2 |
|     3    | goldfish | Dobbin | 0 | 0.05 |
|     4    |   ant   | null | 6 | 0.001 |

```

#### 4.1.5 Comma-Separated Values

Comma-separated value ("CSV") format is a common semi-standard text-based format in which fields are delimited by commas. Spreadsheets and databases are often able to export data in some variant of it. The intention is that TOPCAT can read tables in the version of the format spoken by MS Excel amongst other applications, though the documentation on which it was based was not obtained directly from Microsoft.

The rules for data which it understands are as follows:

- Each row must have the same number of comma-separated fields.
- Whitespace (space or tab) adjacent to a comma is ignored.
- Adjacent commas, or a comma at the start or end of a line (whitespace apart) indicates a null field.
- Lines are terminated by any sequence of carriage-return or newline characters ('\r' or '\n') (a corollary of this is that blank lines are ignored).
- Cells may be enclosed in double quotes; quoted values may contain linebreaks (or any other character); a double quote character within a quoted value is represented by two adjacent double quotes.
- The first line *may* be a header line containing column names rather than a row of data. Exactly the same syntactic rules are followed for such a row as for data rows.

This format is not detected automatically - you must specify that you wish to load a table in `csv` format.

#### 4.1.6 SQL Database Queries

With appropriate configuration, TOPCAT can be used to examine the results of queries on an SQL-compatible relational database.

Database queries can be specified as a string in the form:

```
jdbc:driver-specific-url#sql-query
```

The exact form is dependent on the driver. Here is an example for MySQL:

```
jdbc:mysql://localhost/astro1?user=mbt#SELECT ra, dec FROM swaa WHERE vmag<18
```

which would get a two-column table (the columns being "ra" and "dec"), constructed from certain rows from the table "swaa" in the database "astro1" on the local host, using the access privileges of user mbt.

Fortunately you don't have to construct this by hand, there is an SQL Query Dialogue (Appendix

A.5.3) to assist in putting it together.

Note that TOPCAT does not view a table in the database directly, but the result of an SQL query on that table. If you want to view the whole table you can use the query

```
SELECT * FROM table-name
```

but be aware that such a query might be expensive on a large table.

Use of SQL queries requires some additional configuration of TOPCAT; see Section 9.3.

### 4.1.7 World Data Center

Some support is provided for files produced by the World Data Centre for Solar Terrestrial Physics. The format itself apparently has no name, but files in this format look something like the following:

```
Column formats and units - (Fixed format columns which are single space separated.)
-----
Datetime (YYYY mm dd HHMMSS)           %4d %2d %2d %6d      -
aa index - 3-HOURLY (Provisional)       %1s                 nT
2000 01 01 000000 67
2000 01 01 030000 32
...
```

Support for WDC tables is experimental - it may not be very robust.

This format is not detected automatically - you must specify that you wish to load a table in `csv` format.

## 4.2 Supported Output Formats

Writing out tables from TOPCAT is done using the Save Table Window. In general you have to specify the format in which you want the table to be output by selecting from the Save Window's **Table Output Format** selector; the following sections describe the possible choices. In some cases there are variants within each format - these are described as well.

The program has no "native" file format, but if you have no particular preference about which format to save tables to, FITS is a good choice. Uncompressed FITS tables do not in most cases have to be read all the way through (they are 'mapped' into memory), which makes them very fast to load up. The FITS format which is written by default (also known as "FITS-plus") also uses a trick to store extra metadata, such as table parameters and UCDS in a way TOPCAT can read in again later (see Section 4.2.1). These files are quite usable as normal FITS tables by other applications, but they will only be able to see the limited metadata stored in the FITS headers. If you want to write to a format which retains all metadata in a portable format, then one of the Section 4.2.2 formats might be better.

### 4.2.1 FITS

When saving in FITS format a new file is written consisting of two HDUs (Header+Data Units): a primary one (required by the FITS standard), and a single extension of type BINTABLE containing the table data.

There are two variants of this format:

#### **fits-basic**

The primary HDU contains only very minimal headers and no data.

#### **fits-plus**

The primary HDU contains an array of bytes which stores the full table metadata as the text of a VOTable document, along with headers that mark this has been done. Most FITS table readers will ignore this altogether and treat the file just as if it contained only the table. When TOPCAT (or other STIL-based applications) read it however, they read out the metadata and make it available for use. In this way you can store your data in the efficient and widely portable FITS format without losing the additional metadata such as table parameters, column UCDS, lengthy column descriptions etc that may be attached to the table. Other, more standard schemes exist for combining the benefits of FITS and VOTable, but suffer from some disadvantages: `votable-fits-inline` is hard to process efficiently (in particular the data cannot easily be mapped into memory) and `votable-fits-href` requires that you keep your data in two separate files, which can get separated from each other. If you want to ensure that the metadata are available to other VOTable-aware programs, you should use one of the normal VOTable formats (Section 4.2.2).

In general, you can just let TOPCAT detect the format automatically and not worry about which of these variants is being used - if `fits-plus` is being used you just get some hidden benefits.

#### 4.2.2 VOTable

When a table is saved to VOTable format, a document conforming to the VOTable 1.0 specification containing a single TABLE element within a single RESOURCE element is written.

There are a number of variants which determine the form in which the table data (DATA element) is written:

**votable-tabledata**

TABLEDATA element (pure XML)

**votable-binary-inline**

BINARY element containing base64-encoded data within the document

**votable-fits-href**

FITS element containing a reference to an external newly-written FITS file (with a name derived from that of the VOTable document)

**votable-binary-href**

BINARY element containing a reference to an external newly-written binary file (with a name derived from that of the VOTable document)

**votable-fits-inline**

FITS element containing base64-encoded data within the document

See the VOTable specification (<http://www.ivoa.net/Documents/latest/VOT.html>) for more explanation of what these variants mean. They can all be read by the VOTable input handler.

#### 4.2.3 ASCII

Tables can be written using a format which is compatible with the ASCII input format. It writes as plainly as possible, so should stand a good chance of being comprehensible to other programs which require some sort of plain text rendition of a table.

The first line is a comment (starting with a "#" character) which names the columns, and an attempt is made to line up data in columns using spaces. Here is an example of a short table written in this format:

```
# index Species Name Legs Height Mammal
1 pig Bland 4 0.8 true
2 cow Daisy 4 2.0 true
3 goldfish Dobbin 0 0.05 false
4 ant " " 6 0.0010 false
```

```

5   ant   ""   6   0.0010 false
6   human Mark 2   1.9   true
    
```

#### 4.2.4 Text

Tables can be written to a simple text-based format which is designed to be read by humans. No reader exists for this format.

Here is an example of a short table written in this format:

```

+-----+-----+-----+-----+-----+-----+
| index | Species | Name | Legs | Height | Mammal |
+-----+-----+-----+-----+-----+-----+
| 1     | pig     | Bland | 4     | 0.8    | true   |
| 2     | cow     | Daisy | 4     | 2.0    | true   |
| 3     | goldfish | Dobbin | 0     | 0.05   | false  |
| 4     | ant     |       | 6     | 0.0010 | false  |
| 5     | ant     |       | 6     | 0.0010 | false  |
| 6     | human   | Mark  | 2     | 1.9    | true   |
+-----+-----+-----+-----+-----+-----+
    
```

#### 4.2.5 Comma-Separated Values

Tables can be written to the semi-standard comma-separated value (CSV) format, described in more detail in Section 4.1.5. This can be useful for importing into certain external applications, such as some spreadsheets or databases. The first row written contains the column names.

#### 4.2.6 SQL Tables

With appropriate configuration, TOPCAT can write out tables as new tables in an SQL-compatible relational database.

For writing, the location is specified as the following URL:

```
jdbc:driver-specific-url#new-table-name
```

The exact form is dependent on the driver. Here is an example for MySQL:

```
jdbc:mysql://localhost/astro1?user=mbt#newtab
```

which would write the current contents of the browser into a new table named "newtab" in the database "astro1" on the local host with the access privileges of user mbt.

Fortunately you do not have to construct this URL by hand, there is an SQL dialogue box to assist in putting it together.

Use of SQL queries requires some additional configuration of TOPCAT; see Section 9.3.

#### 4.2.7 HTML

A table can be written out as an HTML 3.2 TABLE element, suitable for use as a web page or insertion into one.

There are two variants:

##### HTML

A freestanding HTML document, complete with HTML, HEAD and BODY tags is output.

##### HTML-element

Only the TABLE element representing the table is output; this should normally be embedded in a larger HTML document before use.

### 4.2.8 LaTeX

A table can be written out as a LaTeX `tabular` environment, suitable for insertion into a document intended for publication.

There are two variants:

#### LaTeX

The `tabular` element alone is output; this will have to be embedded in a larger LaTeX document before use.

#### LaTeX-document

A freestanding LaTeX document, consisting of the `tabular` within a `table` within a document is output.

Obviously, this isn't so suitable for very large tables.

### 4.2.9 Mirage Format

Mirage (<http://www.bell-labs.com/project/mirage/index.html>) is a powerful standalone java tool developed at Bell Labs for analysis of multidimensional data. It uses its own file format for input. TOPCAT can write tables in the input format which Mirage uses, so that you can prepare tables in TOPCAT and write them out for subsequent use by Mirage.

It is also possible in principle to launch Mirage directly from within TOPCAT, using the **Export To Mirage** item on the Control Window's **File** menu; this will cause Mirage to start up viewing the currently selected Apparent Table. In order for this to work the Mirage classes must be on your classpath (see Section 9.2.1) when TOPCAT is run.

There appears to be a bug in Mirage which means this does not always work - sometimes Mirage starts up with no data loaded into it. In this case you will have to save the data to disk in Mirage format, start up Mirage separately, and load the data in using the **New Dataset** item in Mirage's **Console** menu.

Note that when Mirage has been launched from TOPCAT, exiting Mirage or closing its window will exit TOPCAT as well.

### 4.3 Custom I/O Formats

It is in principle possible to configure TOPCAT to work with table file formats other than the ones listed in this section. It does not require any upgrade of TOPCAT itself, but you have to write or otherwise acquire an input and/or output handler for the table format in question.

The steps that you need to take are:

1. Write java classes which constitute your input and/or output handler
2. Ensure that these classes are available on your classpath while TOPCAT is running (see Section 9.2.1)
3. Set the `startable.readers` and/or `startable.writers` system property to the name of the handler classes (see Section 9.2.3)

Explaining how to write such handlers is beyond the scope of this document - see the user document and javadocs for STIL (<http://www.starlink.ac.uk/stil/>).

## 5 Joins and Matches

TOPCAT allows you to join two or more tables together to produce a new one in a variety of ways, and also to identify "similar" rows within a single table according to their cell contents. This section describes the facilities for performing these related operations.

There are two basic ways to join tables together: top-to-bottom and side-by-side. A top-to-bottom join (which here I call **concatenation**) is fairly straightforward in that it just requires you to decide which columns in one table correspond to which columns in the other. A side-by-side join is more complicated - it is rarely the case that row  $i$  in the first table should correspond to row  $i$  in the second one, so it is necessary to provide some criteria for deciding which (if any) row in the second table corresponds to a given row in the first. In other words, some sort of **matching** between rows in different tables needs to take place. This corresponds to what is called a *join* in database technology. Matching rows within a single table is a useful operation which involves many of the same issues, so that is described here too.

### 5.1 Concatenating Tables

Two tables can be concatenated using the Concatenation Window, which just requires you to specify the two tables to be joined, and for each column in the first ("Base") table, which column in the second ("Appended") table (if any) corresponds to it. The Apparent Table (Section 3) is used in each case. The resulting table, which is added to the list of known tables in the Control Window, has the same columns as the Base table, and a number of rows equal to the sum of the number of rows in the Base and Appended tables.

As a very simple example, concatenating these two tables:

Messier	RA	Dec	Name
-----	--	---	----
97	168.63	55.03	Owl Nebula
101	210.75	54.375	Pinwheel Galaxy
64	194.13	21.700	Black Eye Galaxy

and

RA2000	DEC2000	ID
-----	-----	--
185.6	58.08	M40
186.3	18.20	M85

with the assignments RA->RA2000, Dec->DEC2000 and Messier->ID would give:

Messier	RA	Dec	Name
-----	--	---	----
97	168.63	55.03	Owl Nebula
101	210.75	54.375	Pinwheel Galaxy
64	194.13	21.700	Black Eye Galaxy
M40	185.6	58.08	
M85	183.6	18.20	

Of course it is the user's responsibility to ensure that the correspondance of columns is sensible (that the two corresponding columns mean the same thing).

You can perform a concatenation using the Concatenation Window; obtain this using the **Concatenate Tables** () button in the Control Window.

### 5.2 Matching Rows Between Tables

When joining two tables side-by-side you need to identify which row(s) in one correspond to which row(s) in the other. Conceptually, this is done by looking at each row in the first table, somehow identifying in the second table which row "refers to the same thing", and putting a new row in the

joined table which consists of all the fields of the row in the first table, followed by all the fields of its matched row in the second table. The resulting table then has a number of columns equal to the sum of the number of columns in both input tables.

In practice, there are a number of complications. For one thing, each row in one table may be matched by zero, one or many rows in the other. For another, defining what is meant by "referring to the same thing" may not be straightforward. There is also the problem of actually identifying these matches in a relatively efficient way (without explicitly comparing each row in one table with each row in the other, which would be far too slow for large tables).

A common example is the case of matching two object catalogues - suppose we have the following catalogues:

Xpos	Ypos	Vmag
----	----	----
1134.822	599.247	13.8
659.68	1046.874	17.2
909.613	543.293	9.3

and

x	y	Bmag
-	-	----
909.523	543.800	10.1
1832.114	409.567	12.3
1135.201	600.100	14.6
702.622	1004.972	19.0

and we wish to combine them to create one new catalogue with a row for each object which appears in both tables. To do this, you have to specify what counts as a match - in this case let's say that a row in one table matches (refers to the same object as) a row in the other if the distance between the positions indicated by their X and Y coordinates matches to within one unit ( $\sqrt{(X_{\text{pos}}-x)^2 + (Y_{\text{pos}}-y)^2} \leq 1$ ). Then the catalogue we will end up with is:

Xpos	Ypos	Vmag	x	y	Bmag
----	----	----	-	-	----
1134.822	599.247	13.8	1135.201	600.100	14.6
909.613	543.293	9.3	909.523	543.800	10.1

There are a number of variations on this however - your match criteria might involve sky coordinates instead of Cartesian ones (or not be physical coordinates at all), you might want to match more than two tables, you might want to identify groups of matching objects in a single table, you might want the output to include rows which don't match as well...

The Match Window allows you to specify

- Which tables are to be matched
- What the criteria are for matching rows
- What to do for rows that don't have exactly one match
- What rows to include in the output table

and to start the matching operation. Depending on the type of match chosen, some additional columns may be appended to the resulting table giving additional details on how the match went. Usually, the 'match score' is one of these; The exact value and meaning of this column depends on the match, but it typically gives the distance between the matched points in some sensible units; the smaller the value, the better the match. You can find out exactly what this score means by examining the column's description in the Columns Window. Columns in the resulting table retain their original names unless that would lead to ambiguity, in which case a disambiguating suffix "\_1" or "\_2" is added to the column name.

To match two tables, use the **Pair Match** () button in the Control Window; to match more tables than two at once, use the other options on the Control Window's **Join** menu.

### 5.3 Matching Rows Within a Table

Although the effect is rather different, searching through a single table for rows which match each other (refer to the same object, as explained above) is a similar process and requires much of the same information to be specified, mainly, what counts as a match. You can do this using the Internal Match Window, obtained by using the **Internal Match** (  ) button in the Control

Window.

### 5.4 Notes on Matching

This section provides a bit more detail on the how the row matching is done. It is designed to give a rough idea to interested parties; it is *not* a tutorial description from first principles of how it all works.

The basic algorithm for matching is based on dividing up the space of possibly-matching rows into an (indeterminate) number of bins. These bins will typically correspond to disjoint cells of a physical or notional coordinate space, but need not do so. In the first step, each row of each table is assessed to determine which bins might contain matches to it - this will generally be the bin that it falls into and any "adjacent" bins within a distance corresponding to the matching tolerance. A reference to the row is associated with each such bin. In the second step, each bin is examined, and if two or more rows are associated with it every possible pair of rows in the associated set is assessed to see whether it does in fact constitute a matched pair. This will identify all and only those row pairs which are related according to the selected match criteria. During this process a number of optimisations may be applied depending on the details of the data and the requested match.

This means that the matching algorithm is basically an  $O(N \log(N))$  process, where  $N$  is the total number of rows in all the tables participating in a match. This is good news, since the naive interpretation would be  $O(N^2)$ . This can break down however if the matching tolerance is such that the number of rows associated with some or most bins gets large, in which case an  $O(M^2)$  component can come to dominate, where  $M$  is the number of rows per bin. The average number of rows per bin is reported in the logging while a match is proceeding, so you can keep an eye on this.

For more detail on the matching algorithms, see the javadocs for the `uk.ac.starlink.table.join` package, or contact the author.

## 6 Algebraic Expression Syntax

TOPCAT allows you to enter algebraic expressions in a number of contexts:

1. To define a new column in terms of existing columns in the Synthetic Column dialogue
2. To define a new Row Subset (Section 3.1) on the basis of table data in the Algebraic Subset dialogue
3. To define a custom Activation Action (Section 7) in the Activation dialogue.
4. When faced with a column selector for plotting or other purposes, in some cases you can type in an expression rather than selecting or typing a simple column name.

This is a powerful feature which permits you to manipulate and select table data in very flexible ways - you can think of it like a sort of column-oriented spreadsheet. The syntax for entering these expressions is explained in this section.

What you write are actually expressions in the Java language, which are compiled into Java bytecode before evaluation. However, this does not mean that you need to be a Java programmer to write them. The syntax is pretty similar to C, but even if you've never programmed in C most simple things, and some complicated ones, are quite intuitive.

The following explanation gives some guidance and examples for writing these expressions. Unfortunately a complete tutorial on writing Java is beyond the scope of this document, but it should provide enough information for even a novice to write useful expressions.

The expressions that you can write are basically any function of all the column values and subset inclusion flags which apply to a given row; the function result can then define the per-row value of a new column, or the inclusion flag for a new subset, or the action to be performed when a row is activated by clicking on it. If the built-in operators and functions are not sufficient, or it's unwieldy to express your function in one line of code, you can add new functions by writing your own classes - see Section 6.8.

**Note:** if Java is running in an environment with certain security restrictions (a security manager which does not permit creation of custom class loaders) then algebraic expressions won't work at all, and the buttons which allow you to enter them will be disabled.

### 6.1 Referencing Cell Values

To create a useful expression for a cell in a column, you will have to refer to other cells in different columns of the same table row. You can do this in two ways:

#### By Name

The Name of the column may be used if it is unique (no other column in the table has the same name) and if it has a suitable form. This means that it must have the form of a Java variable - basically starting with a letter and continuing with letters or numbers. In particular it cannot have any spaces in it. The underscore and currency symbols count as letters for this purpose. Column names are treated case-insensitively.

#### By \$ID

The "\$ID" identifier of the column may always be used to refer to it; this is a useful fallback if the column name isn't suitable for some reason (for instance it contains spaces or is not unique). This is just a "\$" sign followed by a unique integer assigned by the program to each column when it is first encountered. You can find out the \$ID identifier by looking in the Columns Window.

There is a special column whose name is "Index" and whose \$ID is "\$0". The value of this is the same as the row number in the unsorted table (the grey numbers on the left of the grid in the Data

Window), so for the first column in the unsorted table it's 1, for the second it's 2, and so on.

The value of the variables so referenced will be a primitive (boolean, byte, short, char, int, long, float, double) if the column contains one of the corresponding types. Otherwise it will be an Object of the type held by the column, for instance a String. In practice this means: you can write the name of a column, and it will evaluate to the numeric (or string) value that that column contains in each row. You can then use this in normal algebraic expressions such as "B\_MAG - U\_MAG" as you'd expect.

## 6.2 Referencing Row Subset Flags

If you have any Row Subsets defined you can also access the value of the boolean (true/false) flag indicating whether the current row is in each subset. Again there are two ways of doing this:

### By Name

The name assigned to the subset when it was created can be used if it is unique and if it has a suitable form. The same comments apply as to column names above.

### By `_ID`

The "`_ID`" identifier of the subset may always be used to refer to it. Like the "`$ID`" identifier for columns above, this is a unique integer preceded by a special symbol, this time the underscore, "`_`".

**Note:** in early versions of TOPCAT the hash sign ("`#`") was used instead of the underscore for this purpose; the hash sign no longer has this meaning.

In either case, the value will be a boolean value; these can be useful in conjunction with the conditional "`? :`" operator or when combining existing subsets using logical operators to create a new subset.

## 6.3 Null Values

When no special steps are taken, if a null value (blank cell) is encountered in evaluating an expression (usually because one of the columns it relies on has a null value in the row in question) then the result of the expression is also null.

It is possible to exercise more control than this, but it requires a little bit of care, because the expressions work in terms of primitive values (numeric or boolean ones) which don't in general have a defined null value. The name "null" in expressions gives you the java `null` reference, but this cannot be matched against a primitive value or used as the return value of a primitive expression.

For most purposes, the following two tips should enable you to work with null values:

### Testing for null

To test whether a column contains a null value, prepend the string "`NULL_`" (use upper case) to the column name or `$ID`. This will yield a boolean value which is true if the column contains a blank or a floating point NaN (not-a-number) value, and false otherwise.

### Returning null

To return a null value from a numeric expression, use the name "`NULL`" (upper case). To return a null value from a non-numeric expression (e.g. a String column) use the name "`null`" (lower case).

Null values are often used in conjunction with the conditional operator, "`? :`"; the expression

```
test ? tval : fval
```

returns the value `tval` if the boolean expression `test` evaluates true, or `fval` if `test` evaluates false. So for instance the following expression:

```
Vmag == -99 ? NULL : Vmag
```

can be used to define a new column which has the same value as the `Vmag` column for most values, but if `Vmag` has the "magic" value -99 the new column will contain a blank. The opposite trick (substituting a blank value with a magic one) can be done like this:

```
NULL_Vmag ? -99 : Vmag
```

Some more examples are given in Section 6.7.

## 6.4 Operators

The operators are pretty much the same as in the C language. The common ones are:

### Arithmetic

- +** (add)
- (subtract)
- \*** (multiply)
- /** (divide)
- %** (modulus)

### Logical

- !** (not)
- &&** (and)
- ||** (or)
- ^** (exclusive-or)
- ==** (numeric identity)
- !=** (numeric non-identity)
- <** (less than)
- >** (greater than)
- <=** (less than or equal)
- >=** (greater than or equal)

### Numeric Typecasts

- (byte)** (numeric -> signed byte)
- (short)** (numeric -> 2-byte integer)
- (int)** (numeric -> 4-byte integer)
- (long)** (numeric -> 8-byte integer)
- (float)** (numeric -> 4-type floating point)
- (double)** (numeric -> 8-byte floating point)

Note you may find the numeric conversion functions in the **Maths** class described in Appendix B.1 below more convenient for numeric conversions than these.

### Other

- +** (string concatenation)
- []** (array dereferencing)
- ?:** (conditional switch)
- instanceof** (class membership)

## 6.5 Functions

Many functions are available for use within your expressions, covering standard mathematical and

trigonometric functions, arithmetic utility functions, type conversions, and some more specialised astronomical ones. You can use them in just the way you'd expect, by using the function name (unlike column names, this is case-sensitive) followed by comma-separated arguments in brackets, so

```
max ( IMAG , JMAG )
```

will give you the larger of the values in the columns IMAG and JMAG, and so on.

The functions are grouped into the following classes:

### **Times**

Functions for conversion of time values between various forms. The forms used are

#### **Modified Julian Date (MJD)**

A continuous measure in days since midnight at the start of 17 November 1858. Based on UTC.

#### **ISO 8601**

A string representation of the form `yyyy-mm-ddThh:mm:ss.s`, where the `T` is a literal character (a space character may be used instead). Based on UTC.

#### **Julian Epoch**

A continuous measure based on a Julian year of exactly 365.25 days. For approximate purposes this resembles the fractional number of years AD represented by the date. Sometimes (but not here) represented by prefixing a 'J'; J2000.0 is defined as 2000 January 1.5 in the TT timescale.

#### **Besselian Epoch**

A continuous measure based on a tropical year of about 365.2422 days. For approximate purposes this resembles the fractional number of years AD represented by the date. Sometimes (but not here) represented by prefixing a 'B'.

Therefore midday on the 25th of October 2004 is `2004-10-25T12:00:00` in ISO 8601 format, 53303.5 as an MJD value, 2004.81588 as a Julian Epoch and 2004.81726 as a Besselian Epoch.

Currently this implementation cannot be relied upon to better than a millisecond.

### **Strings**

String manipulation and query functions.

### **Maths**

Standard mathematical and trigonometric functions.

### **Formats**

Functions for formatting numeric values.

### **Coords**

Functions for angle transformations and manipulations. In particular, methods for translating between radians and HH:MM:SS.S or DDD:MM:SS.S type sexagesimal representations are provided.

### **Conversions**

Functions for converting between strings and numeric values.

### **Arithmetic**

Standard arithmetic functions including things like rounding, sign manipulation, and maximum/minimum functions.

A listing of the functions in these classes is given in Appendix B.1, and complete documentation on them is available within TOPCAT from the Available Functions Window.

### 6.5.1 Technical Note

This note provides a bit more detail for Java programmers on what is going on here; only read on if you want to understand how the use of functions in TOPCAT algebraic expressions relates to normal Java code.

The expressions which you write are compiled to Java bytecode when you enter them (if there is a 'compilation error' it will be reported straight away). The functions listed in the previous subsections are all the `public static` methods of the classes which are made available by default. The classes listed are all in the packages `uk.ac.starlink.ttools.func` and `uk.ac.starlink.topcat.func` (`uk.ac.starlink.topcat.func.Strings` etc). However, the public static methods are all imported into an anonymous namespace for bytecode compilation, so that you write `sqrt(x)` and not `Maths.sqrt(x)`. The same happens to other classes that are imported (which can be in any package or none) - their public static methods all go into the anonymous namespace. Thus, method name clashes are a possibility.

This cleverness is all made possible by the rather wonderful JEL (<http://galaxy.fzu.cz/JEL/>).

### 6.6 Instance Methods

There is another category of functions which can be used apart from those listed in the previous section. These are called, in Java/object-oriented parlance, "instance methods" and represent functions that can be executed on an object.

It is possible to invoke any of its public instance methods on any object (though not on primitive values - numeric and boolean ones). The syntax is that you place a "." followed by the method invocation after the object you want to invoke the method on, hence `NAME.substring(3)` instead of `substring(NAME,3)`. If you know what you're doing, feel free to go ahead and do this. However, most of the instance methods you're likely to want to use have equivalents in the normal functions listed in the previous section, so unless you're a Java programmer or feeling adventurous, you are probably best off ignoring this feature.

### 6.7 Examples

Here are some general examples. They could be used to define synthetic columns or (where numeric) to define values for one of the axes in a plot.

#### Average

```
(first + second) * 0.5
```

#### Square root

```
sqrt(variance)
```

#### Angle conversion

```
radiansToDegrees(DEC_radians)
degreesToRadians(RA_degrees)
```

#### Conversion from string to number

```
parseInt($12)
parseDouble(ident)
```

#### Conversion from number to string

```
toString(index)
```

#### Conversion between numeric types

```
toShort(obs_type)
toDouble(range)
```

*or*

```
(short) obs_type
(double) range
```

### Conversion from sexagesimal to radians

```
hmsToRadians(RA1950)
dmsToRadians(decDeg,decMin,decSec)
```

### Conversion from radians to sexagesimal

```
radiansToDms($3)
radiansToHms(RA,2)
```

### Outlier clipping

```
min(1000, max(value, 0))
```

### Converting a magic value to null

```
jmag == 9999 ? NULL : jmag
```

### Converting a null value to a magic one

```
NULL_jmag ? 9999 : jmag
```

### Taking the third scalar element from an array-valued column

```
psfCounts[2]
```

and here are some examples of boolean expressions that could be used to define row subsets (or to create boolean synthetic columns):

#### Within a numeric range

```
RA > 100 && RA < 120 && Dec > 75 && Dec < 85
```

#### Within a circle

```
$2*$2 + $3*$3 < 1
skyDistance(ra0,dec0,degreesToRadians(RA),degreesToRadians(DEC))<15*ARC_MINUTE
```

#### First 100 rows

```
index <= 100
```

#### Every tenth row

```
index % 10 == 0
```

#### String equality/matching

```
equals(SECTOR, "ZZ9 Plural Z Alpha")
equalsIgnoreCase(SECTOR, "zz9 plural z alpha")
startsWith(SECTOR, "ZZ")
contains(ph_qual, "U")
```

#### String regular expression matching

```
matches(SECTOR, "[XYZ] Alpha")
```

#### Combining subsets

```
(_1 && _2) && ! _3
```

#### Test for non-blank value

```
! NULL_ellipticity
```

## 6.8 Adding User-Defined Functions

The functions provided by default for use with algebraic expressions, while powerful, may not provide all the operations you need. For this reason, it is possible to write your own extensions to the expression language. In this way you can specify arbitrarily complicated functions. Note however that this will only allow you to define new columns or subsets where each cell is a function only of the other cells in the same row - there is no way to define a value in one row as a function of values in other rows.

In order to do this, you have to write and compile a (probably short) program in the Java language. A full discussion of how to go about this is beyond the scope of this document, so if you are new to Java and/or programming you may need to find a friendly local programmer to assist (or mail the author). The following explanation is aimed at Java programmers, but may not be incomprehensible to non-specialists.

The steps you need to follow are:

1. Write and compile a class containing one or more static public methods representing the function(s) required
2. Make this class available on the application's classpath at runtime as described in Section 9.2.1
3. Specify the class's name to the application, *either* as the value of the `jel.classes` or `jel.classes.activation` system properties (colon-separated if there are several) as described in Section 9.2.3 *or* during a run using the Available Function Window's **IAdd Class** ()

button

Any public static methods defined in the classes thus specified will be available for use in the Synthetic Column, Algebraic Subset or (in the case of activation functions only) Activation Window windows. They should be defined to take and return the relevant primitive or Object types for the function required (in the case of activation functions the return value should normally be a short log string).

For example, a class written as follows would define a three-value average:

```
public class AuxFuncs {
    public static double average3( double x, double y, double z ) {
        return ( x + y + z ) / 3.0;
    }
}
```

and the expression "`average3($1,$2,$3)`" could then be used to define a new synthetic column, giving the average of the first three existing columns. Exactly how you would build this is dependent on your system, but it might involve doing something like the following:

1. Writing a file named "AuxFuncs.java" containing the above code
2. Compiling it using a command like "`javac AuxFuncs.java`"
3. Starting up TOPCAT with the flags: "`topcat -Djel.classes=AuxFuncs -classpath .`"

## 7 Activation Actions

As well as seeing the overview of table data provided by a plot or statistics summary, it is often necessary to focus on a particular row of the table, which according to the nature of the table may represent an astronomical object, an event or some other entity. In the Data Window a table row is simply a row of the displayed JTable, and in a plot it corresponds to one plotted point.

If you click on plotted point in one of the graphics windows, or on a row in the Data Window, the corresponding table row will be *activated*. When a row is activated, three things happen:

1. If that row is represented by a point in any open 2- or 3-dimensional scatter plot windows, a visible cursor marker will be drawn centred on that point.
2. If the Data Window is visible, the table will be scrolled to show the row and it will be highlighted
3. If an *activation action* has been defined, it will be invoked

The first two of these mean that you can easily see which point in a plot corresponds to which row in the table and vice versa - just click on one and the other will be highlighted.

The third one can be more complicated. By default, no activation action is set, so nothing else happens, and this may very well be what you want. However, by clicking on the **Activation Action** selector in the Control Window you can bring up the Activation Window which enables you to choose an additional action to take place. There are various options here and various ways to achieve them (see Appendix A.7.4 for more details) but the kinds of actions which are envisaged are to display one or more images or spectra relating to the row you have identified. One of the options available for instance retrieves a postage-stamp image of a few arcminutes around the sky position defined by the row from a SuperCOSMOS all-sky image survey and pops it up in a viewer window. So for instance having spotted an interesting point in a plot of a galaxy catalogue you can click on it, and immediately see a picture to identify its morphological type.

The exact actions you want to perform may be closely tailored to the data you have, for instance you may have a set of spectra on disk named by object ID. It's impossible to cater for such possibilities with a set of pre-packaged options, so you are able to define your own custom actions here. This is done by writing a expression using the syntax described in Section 6. A number of special functions (described in the following subsection) are provided to do things like display an image or a spectrum in a browser (given its filename or URL), or access data from certain data servers on the web, but there is nothing to stop the adventurous plugging in their own external programs so in principle you can configure pretty much anything to happen on the basis of the values in the row that you have activated.

### 7.1 Activation Functions

When defining custom activation actions in the Activation Window, you enter an expression to be invoked on a row when it is activated. This expression uses the syntax defined in Section 6 and can make use of the functions listed in Appendix B.1. However in this case there is an additional list of functions you can use which cause something to happen (for instance displaying an image) rather than just returning a value. The following classes of functions are available:

#### TwoQZ

Specialist functions for use with data from the the 2QZ survey. Spectral data are taken directly from the 2QZ web site at <http://www.2dfquasar.org/> (<http://www.2dfquasar.org/>).

#### System

Executes commands on the local operating system. These are executed as if typed in from the shell, or command line.

#### SuperCosmos

Specialist display functions for use with the SuperCOSMOS survey. These functions display cutout images from the various archives hosted at the SuperCOSMOS Sky Surveys (<http://www-wfau.roe.ac.uk/sss/> (<http://www-wfau.roe.ac.uk/sss/>)). In most cases these cover the whole of the southern sky.

**Splat**

Functions for display of spectra in the external viewer SPLAT.

**Spectrum**

Functions for general display of spectra in a window. Display is currently done using the SPLAT program, if available (<http://www.starlink.ac.uk/splat/> (<http://www.starlink.ac.uk/splat/>)). Recognised spectrum formats include 1-dimensional FITS arrays and NDF files.

**Sog**

Functions for display of images in external viewer SOG (<http://www.starlink.ac.uk/sog/> (<http://www.starlink.ac.uk/sog/>)).

**Sdss**

Specialist display functions for use with the Sloane Digital Sky Server.

**Output**

Functions for simple logging output.

**Mgc**

Specialist functions for use with data from the the Millennium Galaxy Survey.

**Image**

Functions for display of images in a window. Supported image formats include GIF, JPEG, PNG and FITS, which may be compressed. The SoG program (<http://www.starlink.ac.uk/sog/> (<http://www.starlink.ac.uk/sog/>)) will be used if it is available, otherwise a no-frills image viewer will be used instead.

**Browsers**

Displays URLs in web browsers.

**BasicImageDisplay**

Functions for display of graphics-format images in a no-frills viewing window (an `ImageWindow`). Supported image formats include GIF, JPEG, PNG and FITS, which may be compressed.

A listing of the functions in these classes is given in Appendix B.2, and complete documentation on them is available within TOPCAT from the Available Functions Window.

## 8 Tool Interoperability

TOPCAT makes use of a tool interoperability protocol called PLASTIC (Platform for Astronomical InterConnection). This can be used to exchange messages between TOPCAT and other PLASTIC-aware tools such as Aladin, VisIVO and STILTS. The messages which are relevant to TOPCAT are things like "load this table" or "highlight this set of rows".

The communication works by all tools communicating with a central 'hub' process, so a hub must be running in order for the messaging to operate. If a hub is running when TOPCAT starts, it will connect to it automatically, listening for messages sent by other tools. If not, you can start a hub from the **Interop** menu in the Control Window or start one externally and then connect to it using that menu. Other tools will have their own policy for connecting to the hub, but in general it's best to start a hub first before starting up the tools which you want to talk to it. Currently, the usual way to run a hub is to start up the AstroGrid Workbench (<http://software.astrogrid.org/userdocs/workbench.html>) which has a hub that forms part of it. You can run Workbench using Java WebStart from the link above.

The interoperability has two aspects to it: on the one hand TOPCAT can send messages to other applications which cause them to do things, and on the other hand TOPCAT can receive and act on such messages sent by other applications. These are described separately in the subsections below.

The PLASTIC protocol itself is still under development and may undergo changes in the future. It is therefore possible that there may be version compatibility issues which arise between TOPCAT and other PLASTIC-compliant tools and services, so these facilities should probably be regarded as experimental at present.

### 8.1 Messages Sent

This section describes the messages which TOPCAT can send to other tools which understand the PLASTIC protocol, and how to cause them to be sent. The PLASTIC message IDs are listed along with the descriptions; unless you are a tool developer you can probably ignore these.

#### Broadcast Table

The **Broadcast Table** () option on the **Interop** menu in the Control Window will cause the currently selected table to be sent to listening applications. They are invited to load the table in its current form.

Message ID: `ivo://votech.org/votable/load` OR `ivo://votech.org/votable/loadFromURL`

#### Broadcast Subset

The **Broadcast Subset** () button in the Subset Window (Appendix A.3.4) causes the selected subset to be sent to listening applications (only available if one of the subsets is currently selected). They are invited to highlight the rows corresponding to that subset. Note this will only have an effect if the other application(s) are displaying the table that this subset relates to. This will be the case in one of two situations: (1) the table has been loaded from the same URL/filename by the other tool(s) or (2) the other tool(s) have acquired the table because it has already been broadcast using PLASTIC.

Message ID: `ivo://votech.org/votable/showObjects`

#### Broadcast Coordinates

One of the Activation Actions (Section 7) you can choose is **Broadcast Coordinates**. If this is chosen, then every time you select a row (e.g. by clicking on the corresponding point in a plot), other applications are invited to highlight this point in some way, for instance by positioning the cursor on it.

Message ID: `ivo://votech.org/sky/pointAtCoords`

### Broadcast Image

The Density Plot (Appendix A.4.7) produces a 2-d histogram which is actually an image. The **Broadcast Image** () option in the **Export** menu allows you to send this (as a FITS image)

to other applications which can display it in some way. This is a useful supplement to the facilities of the Density Plot window, since it doesn't have very sophisticated image display features (variable colour maps, contour plots etc).

Message ID: `ivo://votech.org/fits/image/loadFromURL`

## 8.2 Messages Received

This section describes the messages which TOPCAT will respond to when it receives them from other applications via the PLASTIC hub. The PLASTIC message IDs are listed along with the descriptions; unless you are a tool developer you can probably ignore these.

### Load Table

Loads a table broadcast by another application. It is added to the list of tables in the Control Window.

Message ID: `ivo://votech.org/votable/load` OR `ivo://votech.org/votable/loadFromURL`

### New Subset

If TOPCAT already has loaded the table identified by the request, it will add a new Row Subset with a name like "plastic-1" to the list of subsets for that table, and will set it as the currently selected one. This has the effect of setting it as the only displayed subset in any open plot windows, as well as changing the current state of the Apparent Table (Section 3).

Message ID: `ivo://votech.org/votable/showObjects`

The following system-level messages are also responded to:

- `ivo://votech.org/test/echo`
- `ivo://votech.org/info/getName`
- `ivo://votech.org/hub/event/HubStopping`
- `ivo://votech.org/info/getIconURL`

## 9 Invoking TOPCAT

Starting up TOPCAT may just be a case of typing "topcat" or clicking on an appropriate icon and watching the Control Window pop up. If that is the case, and it's running happily for you, you can probably ignore this section. What follows is a description of how to start the program up, and various command line arguments and configuration options which can't be changed from within the program. Some examples are given in Section 9.5. Actually obtaining the program is not covered here; please see the TOPCAT web page <http://www.starlink.ac.uk/topcat/>.

There are various ways of starting up TOPCAT depending on how (and whether) it has been installed on your system; some of these are described below.

There may be some sort of short-cut icon on your desktop which starts up the program - in this case just clicking on it will probably work. Failing that you may be able to locate the jar file (probably named `topcat.jar`, `topcat-full.jar` or `topcat-lite.jar`) and click on that. These files would be located in the `java/lib/topcat/` directory in a standard Starjava installation. Note that when you start by clicking on something you may not have the option of entering any of the command line options described below.

Alternatively you will have to invoke the program from the command line. On Unix-like operating systems, you can use the `topcat` script. If you have the full starjava installation, this is probably in the `starjava/java/bin` directory. If you have one of the standalone jar files (`topcat-full.jar` or `topcat-lite.jar`), it should be in the same directory as it/them. If it's not there, you can unpack it from the jar file itself, using a command like `unzip topcat-lite.jar topcat`. If that directory (and java) is on your path then you can write:

```
topcat [java-args] [topcat-args]
```

In this case any arguments which start `-D` or `-X` are assumed to be arguments to the java command, a `-classpath path` defines a class path to be used in addition to the TOPCAT classes, and any remaining arguments are used by TOPCAT.

If you're not running Unix then to start from the command line you will have to use the `java` command itself. The most straightforward way of doing this will look like:

```
java [java-args] -jar path/to/topcat.jar [topcat-args]
```

(or the same for `topcat-full.jar` etc). However **NOTE**: using java's `-jar` flag ignores any other class path information, such as the `CLASSPATH` environment variable or java's `-classpath` flag - see Section 9.2.1.

Note that Java Web Start can also be used to invoke the program without requiring any prior download/installation - sorry, this isn't documented properly here yet.

The meaning of the optional `[topcat-args]` and `[java-args]` sequences are described in Section 9.1 and Section 9.2 below respectively.

### 9.1 TOPCAT Command-line Arguments

You can start TOPCAT from the command line with no arguments - in this case it will just pop up the command window from which you can load in tables. However you may specify flags and/or table locations and formats.

If you invoke the program with the `"-help"` flag you will see the following usage message:

```
Usage: topcat <flags> [[-f <format>] <table> ...]
```

```
General flags:
    -help          print this message and exit
```

```

-version      print component versions etc and exit
-verbose     increase verbosity of reports to console
-demo        start with demo data
-disk        use disk backing store for large tables
-hub         run internal PLASTIC hub
-[no]plastic do [not] connect to running PLASTIC hub
-[no]soap    do [not] start SOAP services
-noserv     don't run any services

```

Optional load dialogue flags:

```

-tree        hierarchy browser
-file        basic file browser
-sql         SQL query on relational database
-cone        cone search dialogue
-registry    VO registry query
-siap        Simple Image Access Protocol queries

```

Useful Java flags:

```

-classpath jar1:jar2.. specify additional classes
-XmxnnnM     use nnn megabytes of memory

```

Auto-detected formats:

```
fits-plus, fits, votable
```

All known formats:

```
fits-plus, fits, votable, ascii, csv, ipac, wdc
```

Useful system properties (-Dname=value - lists are colon-separated):

```

java.io.tmpdir      temporary filespace directory
jdbc.drivers        JDBC driver classes
jel.classes          custom algebraic function classes
jel.classes.activation custom action function classes
star.connectors     custom remote filestore classes
startable.load.dialogs custom load dialogue classes
startable.readers   custom table input handlers
startable.writers   custom table output handlers
startable.storage   default storage policy

```

The meaning of the flags is as follows:

#### **-f <format>**

Signifies that the file(s) named after it on the command line are in a particular file format. Some file formats (VOTable, FITS) can be detected automatically by TOPCAT, but others (including Comma-Separated Values) cannot - see Section 4.1. In this case you have to specify with the `-f` flag what format the named files are in. Any table file on the command line following a `-f <format>` sequence must be in the named format until the next `-f` flag. The names of both the auto-detected formats (ones which don't need a `-f`) and the non-auto-detected formats (ones which do) are given in the usage message you can see by giving the `-help` flag (this message is shown above). You may also use the classname of a class on the classpath which implements the `TableBuilder` interface - see SUN/252.

#### **-help**

If the `-help` (or `-h`) flag is given, TOPCAT will write a usage message and exit straight away.

#### **-version**

If the `-version` flag is given, TOPCAT will print a summary of its version and the versions and availability of some its components, and exit straight away.

#### **-demo**

The `-demo` flag causes the program to start up with a few demonstration tables loaded in. You can use these to play around with its facilities. Note these demo tables are quite small to avoid taking up a lot of space in the installation, and don't contain particularly sensible data, they are just to give an idea.

#### **-disk**

If the `-disk` flag is given then the program will use disk backing storage for caching table data that is read in, rather than keeping it in memory. This means that tables much larger than the heap memory assigned to Java can be used. It may lead to slower processing, but usually the

performance is not greatly reduced. If you find TOPCAT running out of memory (you see `OutOfMemoryErrors` popping up in windows or on the console) then re-running with the `-disk` flag is a good idea. The temporary data files are written in the default temporary directory (defined by the `java.io.tmpdir` system property - often `/tmp` - and deleted when the program exits, unless it exits in an unusual way. Note however that uncompressed FITS binary tables on disk are not read into memory in any case (they are *mapped*) so the `-disk` flag may not make much difference with FITS.

**-verbose**

The `-verbose` (or `-v`) flag increases the level of verbosity of messages which TOPCAT writes to standard output (the console). It may be repeated to increase the verbosity further. The messages it controls are currently those written through java's standard logging system - see the description of the Log Window (Appendix A.7.11) for more information about this.

**-[no]plastic**

Controls whether TOPCAT will attempt to connect to a running PLASTIC hub on startup. Currently, the default is that it does connect if a hub is running. See Section 8.

**-hub**

Causes TOPCAT to run an internal PLASTIC hub. This feature is experimental.

**-[no]soap**

Controls whether TOPCAT will start up a SOAP server which can accept requests using the SOAP protocol to display tables from other applications. Currently, the default is that it does not start a server. This option may be withdrawn in future releases.

**-noserv**

Prevents TOPCAT from running any services. Currently the services which it may run are SOAP and PLASTIC (see above).

Some of the flags control what load dialogues are visible in the Load Window. In fact all of these load dialogues can be accessed from the Load Window's **DataSources** menu as long as the classes are available, but if you specify these flags on the command line, the corresponding button will appear in the main part of the window, making the option more obvious. The load dialogue flags are:

**-tree**

Hierarchy browser (Appendix A.5.2), used for content-sensitive browsing of the filespace (not available with topcat-lite).

**-file**

Basic file browser. This doesn't do much that the Filestore Browser (which is present by default, and can also access remote filespace) can't do, but is provided as a fallback.

**-sql**

SQL query (Appendix A.5.3), used for obtaining tables from an SQL query on a relational database (only available if JDBC is set up correctly).

**-cone**

Cone search dialogue (Appendix A.5.4), used for obtaining catalogues of sources in a region of the sky from remote data servers (not available with topcat-lite).

**-registry**

Registry query dialogue (*experimental*), used for obtaining the results of a query on a VO resource registry as a table (not available with topcat-lite).

**-siap**

Simple Image Access Protocol dialogue (*experimental*), used for obtaining the results of SIAP queries on remote data servers (not available with topcat-lite).

These flags in most circumstances do just the same as adding the relevant dialogue class name to the `startable.load.dialogs` system property (see Section 9.2.3).

Other arguments on the command line are taken to be the locations of tables. Any tables so specified will be loaded into TOPCAT at startup. These locations are typically filenames, but could also be URLs or SQL queries, or perhaps something else. In addition they may contain "fragment identifiers" (with a "#") to locate a table within a given resource, so that for instance the location

```
/my/data/cat1.fits#2
```

means the second extension in the multi-extension FITS file `/my/data/cat1.fits`.

Note that options to Java itself may also be specified on the command-line, as described in the next section.

## 9.2 Java Options

As described above, depending on how you invoke TOPCAT you may be able to specify arguments to Java itself (the "Java Virtual Machine") which affect how it runs. These may be defined on the command line or in some other way. The following subsections describe how to control Java in ways which may be relevant to TOPCAT; they are however somewhat dependent on the environment you are running in, so you may experience OS-dependent variations.

### 9.2.1 Class Path

The classpath is the list of places that Java looks to find the bits of compiled code that it uses to run an application. When running TOPCAT this always has to include the TOPCAT classes themselves - this is part of the usual invocation and is described in Section 9. However, for certain things Java might need to find some other classes, in particular for:

- JDBC drivers (see Section 9.3)
- Providing extended algebraic functions (see Section 6.8)
- Launching Mirage (see Section 4.2.9)
- Installing I/O handlers for new table formats (see Section 4.3)

If you are going to use these facilities you will need to start the program with additional class path elements that point to the location of the classes required. How you do this depends on how you are invoking TOPCAT. If you are using the `topcat` startup script, you can write:

```
topcat -classpath other-paths ...
```

(this adds the given paths to the standard ones required for TOPCAT itself). If you are invoking java directly, then you can either write on the command line:

```
java -classpath path/to/topcat.jar:other-paths
    uk.ac.starlink.topcat.Driver ...
```

or set the CLASSPATH environment variable something like this:

```
setenv CLASSPATH path/to/topcat.jar:other-paths
```

In any case, multiple (extra) paths should be separated by colons in the *other-paths* string.

**Note** that if you are running TOPCAT using java's `-jar` flag, any attempt you make to specify the classpath will be ignored! This is to do with Java's security model. If you need to specify a classpath which includes more than the TOPCAT classes themselves, you can't use `java -jar` (use `java -classpath topcat-lite.jar:... uk.ac.starlink.topcat.Driver` instead).

### 9.2.2 Memory Size

If TOPCAT fails during operation with a message that says something about a

`java.lang.OutOfMemoryError`, then your heap size is too small for what you are trying to do. You will have to run `java` with a bigger heap size using the `-Xmx` flag. Invoking TOPCAT from the `topcat` script you would write something like:

```
topcat -Xmx256M ...
```

or using `java` directly:

```
java -Xmx256M ...
```

which means use up to 256 megabytes of memory (don't forget the "M" for megabyte). JVMs typically default to a heap size of 64M. You probably don't want to specify a heap size larger than the physical memory of the machine that you are running on.

There are other types of memory and tuning options controlled using options of the form `-X<something-or-other>`; if you're feeling adventurous you may be able to find out about these by typing `"java -X"`.

**Note** however: using the `-disk` flag described in Section 9.1 may be a better solution; this makes the program store data from large tables on disk rather than in memory.

### 9.2.3 System properties

System properties are a way of getting information into Java (they are the Java equivalent of environment variables). The following ones have special significance within TOPCAT:

#### **java.io.tmpdir**

The directory in which TOPCAT will write any temporary files it needs. This is usually only done if the `-disk` flag has been specified (see Section 9.1).

#### **jdbc.drivers**

Can be set to a (colon-separated) list of JDBC driver classes using which SQL databases can be accessed (see Section 9.3).

#### **jel.classes**

Can be set to a (colon-separated) list of classes containing static methods which define user-provided functions for synthetic columns or subsets. (see Section 6.8).

#### **jel.classes.activation**

Can be set to a (colon-separated) list of classes containing static methods which define user-provided functions for use in custom activation expressions. (see Section 6.8).

#### **star.connectors**

Can be set to a (colon-separated) list of classes which provide access to remote filesystem implementations. Thus-named classes should implement the `uk.ac.starlink.connect.Connector` interface which specifies how you can log on to such a service and provides a hierarchical view of the filesystem it contains.

#### **startable.load.dialogs**

Can be set to a (colon-separated) list of custom table load dialogue classes. Briefly, you can install your own table import dialogues at runtime by providing classes which implement the `uk.ac.starlink.table.gui.TableLoadDialog` interface and naming them in this property. See STIL documentation for more detail.

#### **startable.readers**

Can be set to a (colon-separated) list of custom table format input handler classes (see Section 4.3).

#### **startable.storage**

Can be set to determine the default storage policy. Setting it to `"disk"` has basically the same effect as supplying the `"-disk"` argument on the TOPCAT command line (see Section 9.1).

#### **startable.writers**

Can be set to a (colon-separated) list of custom table format output handler classes (see Section 4.3).

**votable.strict**

Set `true` for strict enforcement of the VOTable standard when parsing VOTables. This prevents the parser from working round certain common errors, such as missing `arraysize` attributes on FIELD/PARAM elements with `datatype="char"`. False by default.

**apple.laf.useScreenMenuBar**

On the Apple Macintosh platform only, this property controls whether menus appear at the top of the screen as usual for Mac, or at the top of individual windows as usual for Java. By default when using Java 1.5 or later it is set to `true` for TOPCAT, so menus mostly appear at the top of the screen (though it's not true to say that TOPCAT obeys the Mac look and feel completely); if you prefer the more Java-like look and feel, set it to `false`. There are bugs with this feature in Apple's Java 1.4 JRE, so it's set `false` by default in that case, but you can try setting it `true` at your own risk if you like.

To define these properties on the command line you use the `-D` flag, which has the form

```
-D<property-name>=<value>
```

If you're using the TOPCAT startup script, you can write something like:

```
topcat -Djdbc.drivers=org.postgresql.Driver ...
```

or if you're using the `java` command directly:

```
java -Djdbc.drivers=org.postgresql.Driver ...
```

Alternatively you may find it more convenient to write these definitions in a file named `.starjava.properties` in your home directory; the above command-line flag would be equivalent to inserting the line:

```
jdbc.drivers=org.postgresql.Driver
```

in your `.starjava.properties` file.

### 9.3 JDBC Configuration

This section describes additional configuration which must be done to allow TOPCAT to access SQL-compatible relational databases for reading (see Section 4.1.6) or writing (see Section 4.2.6) tables. If you don't need to talk to SQL-type databases, you can ignore the rest of this section. The steps described here are the standard ones for configuring JDBC (which sort-of stands for Java Database Connectivity), described in more detail on Sun's JDBC web page.

To use TOPCAT with SQL-compatible databases you must:

- Have access to an SQL-compatible database locally or over the network
- Have a JDBC driver appropriate for that database
- Install this driver for use with TOPCAT
- Know the format the driver uses for URLs to access database tables
- Have appropriate privileges on the database to perform the desired operations

Installing the driver consists of two steps:

1. Set the `jdbc.drivers` system property to the name of the driver class as described in Section 9.2.3
2. Ensure that the classpath you are using includes this driver class as described in Section 9.2.1

These steps are all standard for use of the JDBC system.

To the author's knowledge, TOPCAT has so far successfully been used with the following RDBMSs and corresponding JDBC drivers:

### MySQL

MySQL 3.23.55 on Linux has been tested with the Connector/J driver version 3.0.8 and seems to work, though tables with very many (hundreds of) columns cannot be written owing to SQL statement length restrictions. Note there is known to be a column metadata bug in version 3.0.6 of the driver which can cause a `ClassCastException` error when tables are written.

### PostgreSQL

PostgreSQL 7.4.1 apparently works with its own driver. Note the performance of this driver appears to be rather poor, at least for writing tables.

### Oracle

You can use Oracle with the JDBC driver that comes as part of its Basic Instant Client Package. However, you *can't* currently use the SQL load/SQL save dialogue boxes to do it. You have to specify a JDBC URL specifying the query to read/table to write as a string in the **Location** field of the normal table load/save dialogue boxes. The URL will look something like

```
jdbc:oracle:thin:@//hostname:1521/database#SELECT ...
```

for querying an existing database (loading) and

```
jdbc:oracle:thin:@//hostname:1521/database#new-table-name
```

for writing a new table (saving).

Other RDBMSs and drivers may or may not work - please let us know the results of any experiments you carry out. Sun maintain a list of JDBC drivers for various databases; it can be found at <http://servlet.java.sun.com/products/jdbc/drivers>.

Here are example command lines to start up TOPCAT using databases known to work.

### PostgreSQL

```
java -classpath topcat-full.jar:pg73jdbc3.jar \
-Djdbc.drivers=org.postgresql.Driver \
uk.ac.starlink.topcat.Driver
```

### MySQL

```
java -classpath topcat-full.jar:mysql-connector-java-3.0.8-bin.jar \
-Djdbc.drivers=com.mysql.jdbc.Driver \
uk.ac.starlink.topcat.Driver
```

### Oracle

```
java -classpath topcat-full.jar:ojdbc14.jar \
-Djdbc.drivers=oracle.jdbc.driver.OracleDriver \
uk.ac.starlink.topcat.Driver
```

## 9.4 Tips for Large Tables

Considerable effort has gone into making TOPCAT capable of dealing with large datasets. In particular it does not in general have to read entire files into memory in order to do its work, so it's not restricted to using files which fit into the java virtual machine's 'heap memory' or into the physical memory of the machine. As a rule of thumb, the program will work with tables up to about a million rows at a reasonable speed; the number of columns is less of an issue (though see below concerning performance). However, the way you invoke the program affects how well it can cope with large tables; you may in some circumstances get a message that TOPCAT has run out of memory (either a popup or a terse "OutOfMemoryError" report on the console), and there are some things you can do about this:

### Use the `-disk` flag

By default, TOPCAT reads the data from tables in most file formats (everything except FITS binary tables) into memory when it loads them. By specifying the `-disk` flag on the command line, you can tell it to use temporary files for storing this data instead. This makes it much less likely to run out of memory. You can achieve the same effect by adding the line `startable.storage=disk` in the `.starjava.properties` in your home directory. This is the best thing to do if you're seeing an out of memory error when loading tables. See Section 9.1, Section 9.2.3.

### Increase Java's heap memory

When a Java program runs, it has a fixed maximum amount of memory that it will use; Java does not really make use of virtual memory. The default maximum is typically 64Mb. You can increase this by using the `-Xmx` flag, followed by the maximum heap memory, for instance `"topcat -Xmx256M"` or `"java -Xmx256M -jar topcat-full.jar"`. Don't forget the "M" to indicate megabytes. It's generally reasonable to increase this value up to nearly the amount of free physical memory in your machine if you need to (taking account of the needs of other processes running at the same time) but attempting any more will usually result in abysmal performance. See Section 9.2.2.

### Use FITS files

Because of the way that FITS files are organised, TOPCAT is able to load tables which are stored as uncompressed FITS binary tables on disk almost instantly regardless of their size (in this case loading just reads the metadata, and any data elements are only read if and when they are required). So if you have a large file stored in VOTable or ASCII-based form which you use often and takes a long time to load, you may wish to convert it to FITS format once for subsequent use. You can do this either by loading it into TOPCAT once and saving it as FITS, or using the separate command-line package STILTS. Note that the "fits-plus" variant which TOPCAT uses by default retains all the metadata that would be stored in a corresponding VOTable, so you won't normally lose information by doing this (see Section 4.2.1). As well as speeding things up, using FITS files will also reduce the need to use `-disk` or `-Xmx` flags as above.

As far as performance goes, the memory size of the machine you're using does make a difference. If the size of the dataset you're dealing with (this is the size of the FITS HDU if it's in FITS format but may be greater or less than the file size for other formats) will fit into unused physical memory then general everything will run very quickly because the operating system can cache the data in memory; if it's larger than physical memory then the data has to keep being re-read from disk and most operations will be much slower. Using column-based storage to improve matters is a project which may be pursued in future releases.

## 9.5 Examples

Here are some examples of invoking TOPCAT from the command line. In each case two forms are shown: one using the `topcat` script, and one using the `jar` file directly. In the latter case, the `java` command is assumed to be on the your path, and the `jar` file itself, assumed in directory `my/tcdir`, might be named `topcat.jar`, `topcat-full.jar`, or something else, but the form of the command is the same.

### No arguments

```
topcat
java -jar topcat.jar
```

### Output usage message

```
topcat -h
java -jar topcat.jar -h
```

**Load a FITS file**

```
topcat testcat.fits
java -jar my/tcdir/topcat.jar testcat.fits
```

**Loading files of various formats**

```
topcat t1.fits -f ascii t2.txt t3.txt -f votable t4.xml
java -jar my/tcdir/topcat.jar t1.fits -f ascii t2.txt t3.txt -f votable t4.xml
```

**Use disk storage format and boosted heap memory**

```
topcat -Xmx256M -disk
java -Xmx256M -jar my/tcdir/topcat.jar -disk
```

**Make custom functions available**

```
topcat -classpath my/funcdir/funcs.jar -Djel.classes=my.ExtraFuncs t1.fits
java -classpath my/tcdir/topcat.jar:my/funcdir/funcs.jar \
  -Djel.classes=func.ExtraFuncs \
  uk.ac.starlink.topcat.Driver t1.fits
```

**Make PostgreSQL database connectivity available**

```
topcat -classpath my/jdbcdir/pg73jdbc3.jar -Djdbc.drivers=org.postgresql.Driver
java -classpath my/tcdir/topcat.jar:my/jdbcdir/pg73jdbc3.jar \
  -Djdbc.drivers=org.postgresql.Driver uk.ac.starlink.topcat.Driver
```

**Use custom I/O handlers**

```
topcat -classpath my/driverdir/drivers.jar \
  -Dstartable.readers=my.MyTableBuilder \
  -Dstartable.writers=my.MyTableWriter \
java -classpath my/tcdir/topcat.jar:my/driverdir/drivers.jar \
  -Dstartable.readers=my.MyTableBuilder \
  -Dstartable.writers=my.MyTableWriter \
  uk.ac.starlink.topcat.Driver
```

The `-Dx=y` definitions can be avoided by putting equivalent `x=y` lines into the `.starjava.properties` in your home directory.

## A TOPCAT Windows

This appendix gives a tour of all the windows that form the TOPCAT application, explaining the anatomy of the windows and the various tools, menus and other controls. Attributes common to many or all windows are described in Appendix A.1, and the subsequent sections describe each of the windows individually.

When the application is running, the **Help For Window** () toolbar button will display the appropriate description for the window on which it is invoked.

### A.1 Common Window Features

This section describes some features which are common to many or all of the windows used in the TOPCAT program.

#### A.1.1 Toolbar

Each window has a toolbar at the top containing various buttons representing actions that can be invoked from the window. Most of them contain the following buttons:

##### Control Window

Ensures that the Control Window is visible on the screen, deiconifying and raising it if necessary. This can be useful if you 'lose' the window behind a proliferation of other ones.

##### Close

Closes the window. This convenience button has the same effect as closing the window in whatever way your graphics platform normally allows. In most cases, closing the window does not lose state associated with it (such as fields filled in); if you recover the window later it will look the same as when you closed it.

##### Help

Pops up a Help browser window, or makes sure it is visible if it has already been opened. The window will display help information relevant to the window in which you pushed this button.

Buttons in the toolbar often appear in menus of the same window as well; you can identify them because they have the same icon. This is a convenience; invoking the action from the toolbar or from the menu will have the same effect.

Often an action will only be possible in certain circumstances, for instance if some rows in the associated JTable have been selected. If the action is not possible (i.e. it would make no sense to invoke it) then the button in the toolbar and the menu option will be greyed out, indicating that it cannot be invoked in the current state.

#### A.1.2 Menus

Most windows have a menu bar at the top containing one or more menus. These menus will usually provide the actions available from the toolbar (identifiable because they have the same icons), and may provide some other less-commonly-required actions too.

Here are some of the menus common to several windows:

**File menu**

Nearly all windows have this menu. At least the following options are available:

 **Close**

Closes the window. This convenience button has the same effect as closing the window in whatever way your graphics platform normally allows. In most cases, closing the window does not lose state associated with it (such as fields filled in); if you recover the window later it will look the same as when you closed it.

 **Exit**

Exits TOPCAT. You will be prompted to confirm this action if tables are loaded, since it might result in loss of data.

**Help menu**

Nearly all windows have this menu. The following options are available:

**Help**

Pops up the Help Window.

 **Help For Window**

Pops up the Help Window; the window will display help information relevant to the window in which the menu appears.

**About TOPCAT**

Pops up a little window giving information on the version and authorship of the program. It also reports on availability of some optional components.

**Display menu**

This menu is available for most windows which display their data using a JTable component. If present, it contains a list of the columns in the JTable with tickboxes next to them - clicking on a column name in this menu toggles whether the column is visible in the window.

**A.1.3 JTables**

MU_ACOSD	MU_D	SIGMU_A	SIGMU_D

**An example JTable**

Many of the windows, including the Data Window, display their data in a Java widget called a **JTable**. This displays a grid of values, with headings for each column, in a window which you can scroll around. Although JTables are used for a number of different things (for instance, showing the

table data themselves in the Data Window and showing the column metadata in the Columns Window), the fact that the same widget is used provides a common look and feel.

Here are some of the things you can do with a JTable:

### Scroll around

Using the scrollbars which may appear to the right and below the table you can scroll around it to see parts which are not initially visible. You can grab the sliders and drag them around by holding the mouse button down while you move it, or click in the slider "trough" one side or other of the current slider position to move a screenful. Under some circumstances the cursor arrow keys and PageUp/PageDown keys may move the table too. If the JTable is small enough to fit within the window the scrollbars may not appear.

### Move columns

By clicking on the header (grey title bit at the top) of a column and dragging it left or right, you can change the order of columns as displayed. In some cases (the Data Window) this actually has the effect of changing the order of the columns in the table; in other cases it is just cosmetic.

### Resize columns

By dragging on the line between row headers you can change the width of the columns in the table.

### Edit cells

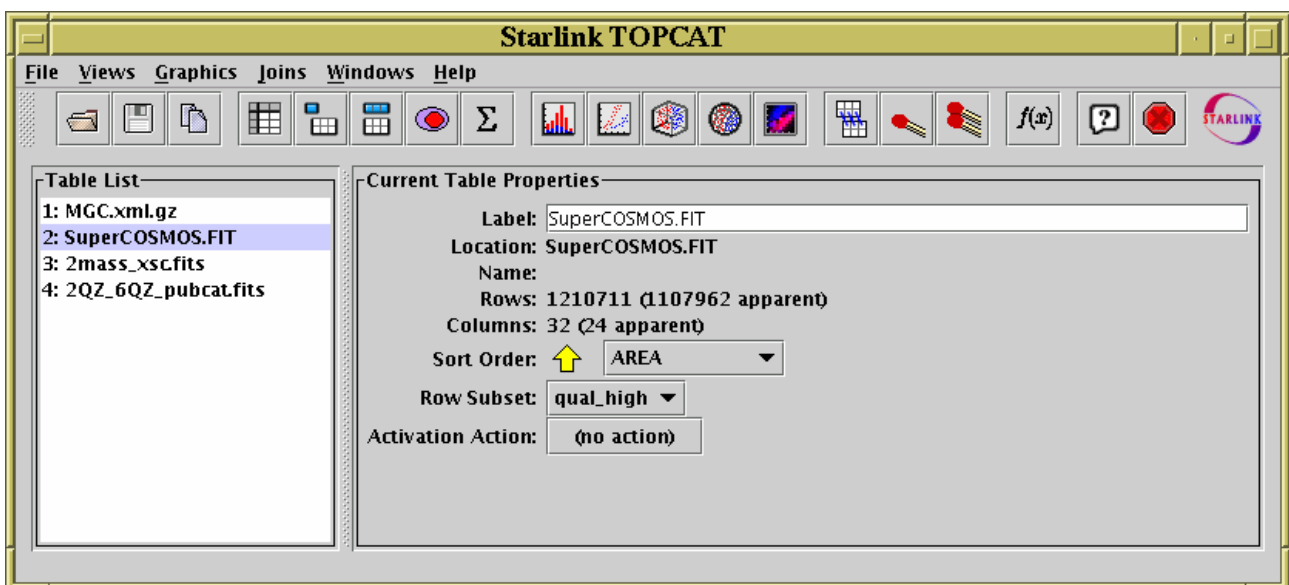

In some cases, cells are editable. If they are, then double-clicking in the cell will begin an edit session for that cell, and pressing Return will confirm that the edit has been made.

### Select rows

Sometimes rows can be highlighted; you can select one row by clicking on it or a number of contiguous rows by clicking and dragging from the first to the last. To add further rows to a set already selected without deselecting the first lot, hold the "Control" key down while you do it.

In some cases where a JTable is displayed, there will be a menu on the menu bar named **Display**. This permits you to select which columns are visible and which are hidden. Clicking on the menu will give you a list of all the available columns in the table, each with a checkbox by it; click the box to toggle whether the column is displayed or not.

## A.2 Control Window

The Control Window

The Control Window is the main window from which all of TOPCAT's activities are controlled. It lists the known tables, summarises their characteristics, and allows you to open other windows for more specialised tasks. When TOPCAT starts up you will see this window - it may or may not have some tables loaded into it according to how you invoked the program.

The window consists of two main parts: the **Table List** panel on the left, and the **Current Table Properties** panel on the right. Tables loaded into TOPCAT are shown in the Table List, each identified by an index number which never changes for a given table, and a label which is initially set from its location, but can be changed for convenience.

One of the tables in the list is highlighted, which means it is the currently selected table; you can change the selection by clicking on an item in the list. Information about the selected table is shown in the properties panel on the right. This shows such things as the number of rows and columns, current sort order, current row subset selection and so on. It contains some controls which allow you to change these properties. Additionally, many of the buttons in the toolbar relate to the currently selected table.

The Table List, Current Table Properties panel, and actions available from the Control Window's toolbar and menus are described in the following subsections.

### A.2.1 Table List

The Table List panel on the left of the Control Window is pretty straightforward - it lists all the tables currently known to TOPCAT. If a new table is introduced by loading it from the Load Window or as a result of some action such as table joining then its name and number will appear in this list. The currently selected table is highlighted - clicking on a different table name (or using the arrow keys if the list has keyboard focus) will change the selection. The properties of the selected table are displayed in the Current Table Properties panel to its right, and a number of the toolbar buttons and menu items refer to it.

If you double-click on a table in the list, or press Return while it is selected, that table's Data Window will appear.

Certain other applications (Treeview, FROG, or even another instance of TOPCAT) can interoperate with TOPCAT using drag-and-drop, and for these the table list is a good place to drag/drop tables. For instance you can drag a table node off of the main panel of Treeview and drop it onto the table list of TOPCAT, and you will be able to use that table as if it had been loaded from disk. You can also paste the filename or URL of a table onto the table list, and it will be loaded.

### A.2.2 Current Table Properties panel

The **Current Table Properties** panel on the right hand side of the Control Window contains a number of controls which relate to the currently selected table and its Apparent properties (Section 3); they will be blank if no table is selected. Here is what the individual items mean:

#### **Label**

The short name associated with the selected table. It is used in the Table List panel and in labelling view windows so you can see which table they refer to. It usually set initially according to where the table came from, but you can change it by typing into the text field.

#### **Location**

The original source of the selected table. This is typically a filename or URL (perhaps abbreviated), but may be something else depending on where the table came from.

#### **Name**

A name associated with the selected table. This may be derived from the table's filename if it

had one or from some naming string stored within the table metadata.

### **Rows**

The number of rows in the selected table. If the current Row Subset does not include all the rows, then an indication of how many are visible within that subset will be given too.

### **Columns**

The number of columns in the selected table. If some are currently hidden (not included in the current Column Set), an indication of how many are visible will be given too.

### **Sort Order**

The column (if any) which determines the current Row Order. A selector shows the column (if any) on which the rows of the Apparent Table are sorted and allows you to choose a different one. The little arrow beside it indicates whether the sort is ascending or descending.

### **Row Subset**

The name of the current Row Subset. A selector shows the name of the subset which determines which rows are part of the Apparent Table and allows you to choose another one. "All" indicates that all rows are included. If you select a new value using this selector, then other windows which display subset-sensitive information for the current table will change their displayed subset to the newly-selected one. However the reverse does not happen - you can change the visible subset in the statistics window for instance or one of the graphics windows and it will not affect the value displayed here.

### **Activation Action**

The currently selected Activation Action (Section 7). The action can be changed by clicking on this button to display the Activation Window.

## **A.2.3 Toolbar Buttons**

There are a number of buttons on the Control Window's toolbar; these are the most convenient way of invoking most of TOPCAT's functions. They are grouped as follows:

### **Import and export**

#### **Load Table**

Pops up the Load Table dialogue which allows you to load a table into TOPCAT. If a table is loaded it becomes the new current table.

#### **Save Table**

Pops up the Save Table dialogue which allows you to write out the current Apparent Table.

#### **Duplicate Table**

Adds a new copy of the current Apparent Table to the list of known tables. This is like loading in the current table again, except that its apparent characteristics become the basic characteristics of the copied one, so for instance whatever is the current row order becomes the natural order of the new one.

## **Table views (see Appendix A.3)**

#### **Data Window**

Displays the table rows and columns in a scrollable viewer so you can see the cell contents themselves.

**Parameters Window**

Displays table "parameters", that is metadata which applies to the whole table.

**Columns Window**

Displays metadata about each column such as data type, units, description, UCDs etc.

**Subsets Window**

Displays the currently defined row subsets (Section 3.1) and enables new ones to be defined.

**Statistics Window**

Displays a window for calculating statistical quantities for the values in each column of the table.

**Graphics windows****Histogram**

Displays a window for plotting 1-d histograms.

**2d Scatter Plot**

Displays a window for plotting 2-d scatter plots.

**3D Scatter Plot**

Displays a window for plotting 3-d scatter plots on Cartesian axes.

**Spherical Scatter Plot**

Displays a window for plotting 3-d scatter plots on spherical polar axes, with or without a radial coordinate.

**Stacked Line Plot**

Displays a window for plotting multiple stacked line plots against a single X coordinate

**Density Map**

Displays a window for plotting 2-d density maps (image-like histograms on a 2-d grid of bins).

**Matching and joining (see Section 5)****Concatenation Window**

Displays a dialog for joining tables top-to-bottom.

**Internal Match Window**

Displays a dialog for finding internal matches between the rows of a table.

**Pair Match Window**

Displays a dialog for joining tables side-by-side by locating rows which match between them.

Note that matches involving more than two tables can be done using the options in the **Joins** menu.

## Miscellaneous

### Available Functions

Displays a window containing all the functions which can be used for writing algebraic expressions (see Section 6).

### Help

Displays the help browser, open at the entry on the Control Window.

### Exit

Queries for confirmation, then exits the application.

## A.2.4 Menu Items

This section describes actions available from the Control Window menus additional to those also available from the toolbar (described in the previous section) and those common to other windows (described in Appendix A.1.2).

The **File** menu contains the following additional actions:

### Discard Table

Removes the current table from the list and closes and forgets any view windows associated with it. A discarded table cannot be reinstated. You will be prompted to confirm this action. Discarding a table in this way *may* free up memory, for other operations, but often will not; whether it does or not depends on the details of where the table comes from.

### Export To Mirage

Starts up the external Mirage application on the current apparent table. This action is only available if Mirage is on your classpath. See Section 4.2.9.

### View Log

Pops up the Log Window to display logging messages generated by the application. Intended mainly for debugging.

The **Windows** menu contains actions for controlling which table view windows (Appendix A.3) are currently visible on the screen. If you have lots of tables and are using various different views of several of them, the number of windows on the screen can get out of hand and it's easy to lose track of what window is where. The actions on this menu do some combination of either hiding or revealing all the various view windows associated with either the selected table or all the other ones. Windows hidden are removed from the screen but if reactivated (e.g. by using the appropriate toolbar button) will come back in the same place and the same state. Revealing all the windows associated with a given table means showing all the view windows which have been opened before (it won't display windows which have never explicitly been opened).

### Show Selected Views Only

Reveal all view windows associated with the currently selected table and hide all others.

### Show Selected Views

Reveal all view windows which are associated with the currently selected table.

**Show All Views**

Reveal all view windows associated with all tables.

**Hide Unselected Views**

Hide all view windows associated with tables other than the currently selected one.

**Hide Selected Views**

Hide all view windows associated with the currently selected table.

**Hide All Views**

Hide all the view windows. If you get really confused, this is a good one to select to clear up your screen prior to reinstating the ones that you actually want to look at.

Note that the **Control Window** item () on menus on all other windows is also useful for window management - it brings back the control window if it's been hidden.

The **Joins** menu, as well as containing the actions for table concatenation, internal matching and pair matching which are available from the toolbar, also gives you the option to join three or four tables at once by matching rows. The multi-table match windows work pretty much the same as the Pair Matching Window, but with more tables.

### A.3 Table View Windows

Many of the windows you will see within TOPCAT display information about a single table. There are several of these, each displaying a different aspect of the table data - cell contents, statistics, column metadata etc. There is one of each type for each of the tables currently loaded, though they won't necessarily all be displayed at once. The title bar of these windows will say something like **TOPCAT(3): Table Columns**, which indicates that it is displaying information about the column metadata for the table labelled "3:" in the Control Window.

To open any of these windows, select the table of interest in the Control Window and click the appropriate toolbar button (or the equivalent item in the **Table Views** menu). This will either open up a new window of the sort you have requested, or if you have opened it before, will make sure it's visible.

If you have lots of tables and are using various different views of several of them, the number of windows on the screen can get out of hand and it's easy to lose track of what window is where. In this case the Control Window's **Windows** menu (described in Appendix A.2.4), or the **File|Control Window** menu item in any of the view windows can be handy to keep them under control.

The following sections describe each of these table view windows in turn.

#### A.3.1 Data Window

	Messier...	Right Ascension	Declination	Common Name	Object Size	Ma
4	51	202.43	47.22	Whirlpool Galaxy	11.0'	8.1
5	53	198.18	18.18		12.6'	7.1
6	63	198.91	42.054	Sunflower Galaxy	15'x9'	8.1
7	64	194.13	21.7	Black Eye Galaxy	10.0'x5.0'	8.1
8	88	187.93	14.43		6.1' X 2.8'	9.1
9	90	189.15	13.18		11.4'x4.7'	9.1
10	91	188.81	14.52		5.0' X 4.1'	10.1
11	94	192.65	41.133		14.0'x12.0'	8.1
12	97	168.63	55.031	Owl Nebula	3.4x3.0	11.1
13	98	187.41	14.07		0.0'x2.7'	10.1

### Data Window

The Data Window presents a `JTable` containing the actual cells of the Apparent Table (Section 3). You can display it using the **Table Data** () button when the chosen table is selected in the

Control Window's Table List.

You can scroll around the table in the usual way. In most cases you can edit cells by double-clicking in them, though some cells (e.g. ones containing arrays rather than scalars) cannot currently be edited. If it looks like an edit has taken place, it has.

There is a grey column of numbers on the left of the `JTable` which gives the row index of each row. This is the value of the special Index column, which numbers each row of the original (not apparent) table starting at 1. If the table has been sorted these numbers may not be in order.

Note that reordering the columns by dragging their headings around will change the order of columns in the table's Column Set and hence the Apparent Table.

If you have table with very many columns it can be difficult to scroll the display sideways so that a column you are interested in is in view. In this case, you can go to the Columns Window and click on the description of the column you are after in the display there. This will have the effect of scrolling the Data Window sideways so that your selected column is visible in the centre of the display here.

The following buttons are available in the toolbar:

### Subset From Selected Rows

Defines a new Row Subset consisting of those rows which are currently highlighted. You can highlight a contiguous group of rows by dragging the mouse over them; further contiguous groups can be added by holding the Control key down while dragging. This action is only available when some rows have been selected.

**Subset From Unselected Rows**

Defines a new Row Subset consisting of those rows which are visible but currently not highlighted. You can highlight a contiguous group of rows by dragging the mouse over them; further contiguous groups can be added by holding the Control key down while dragging. This action is only available when some rows have been selected.

As well as the normal menu, right-clicking over one of the columns in the displayed table will present a **Column Popup Menu**, which provides a convenient way to do some things with the column in question:

**Replace Column**

Pops up a Synthetic Column dialogue to replace this column with a new synthetic one. The dialogue is initialised with the same name, units etc as the selected column, and with an expression that evaluates to its value. You can alter any of these, and the new column will replace the old one, which will be hidden and renamed by appending a suffix like "\_old" to its name.

**New Synthetic Column**

Pops up a Synthetic Column dialogue to insert a new synthetic column just after this one.

**Sort up**

Sorts the table rows according to ascending value of the contents of the column. Only available if some kind of order (e.g. numeric or alphabetic) can sensibly be applied to the column.

**Sort down**

Sorts the table rows according to descending value of the contents of the column. Only available if some kind of order (e.g. numeric or alphabetic) can sensibly be applied to the column.

**Hide**

Hides the column. It can be reinstated from the Columns window.

**Search Column**

For string-valued columns, this option allows you to search for values in a column. If you select it you will be asked to enter a regular expression, and then any row which matches that expression in this column will be selected (highlighted). If there's just one matching column it will be activated as well. The expression obeys normal regular expression syntax, so for instance you'd enter `".*XYZ.*"` to find all rows which contain the string "XYZ".

### A.3.2 Parameters Window

### Parameters Window

The Parameters Window displays metadata which applies to the whole table (rather than that for each column). You can display it using the **Table Parameters** () button when the chosen table is selected in the Control Window's Table List.

In table/database parlance, an item of per-table metadata is often known as a "parameter" of the table. The number of rows and columns will always be listed; some table file formats don't have facilities for storing other table parameter metadata, so there may not be much of interest displayed in this window.

The display is a JTable with one row for each parameter. It indicates the parameter's name, its value, the type of item it is (integer, string etc) and other items of interest such as units, dimensionality or UCD if they are defined. If a column of the table has no entries (for instance, the Units column might be empty because none of the parameters has had units defined for it) then that column may be absent from the display - in this case the **Display** menu can be used to reveal it.

You can edit some parameter values and descriptions by double-clicking on them as usual.

The following items are available in the toolbar:

#### Add Parameter

Pops up a New Parameter Window to allow you to add a new parameter to the table.

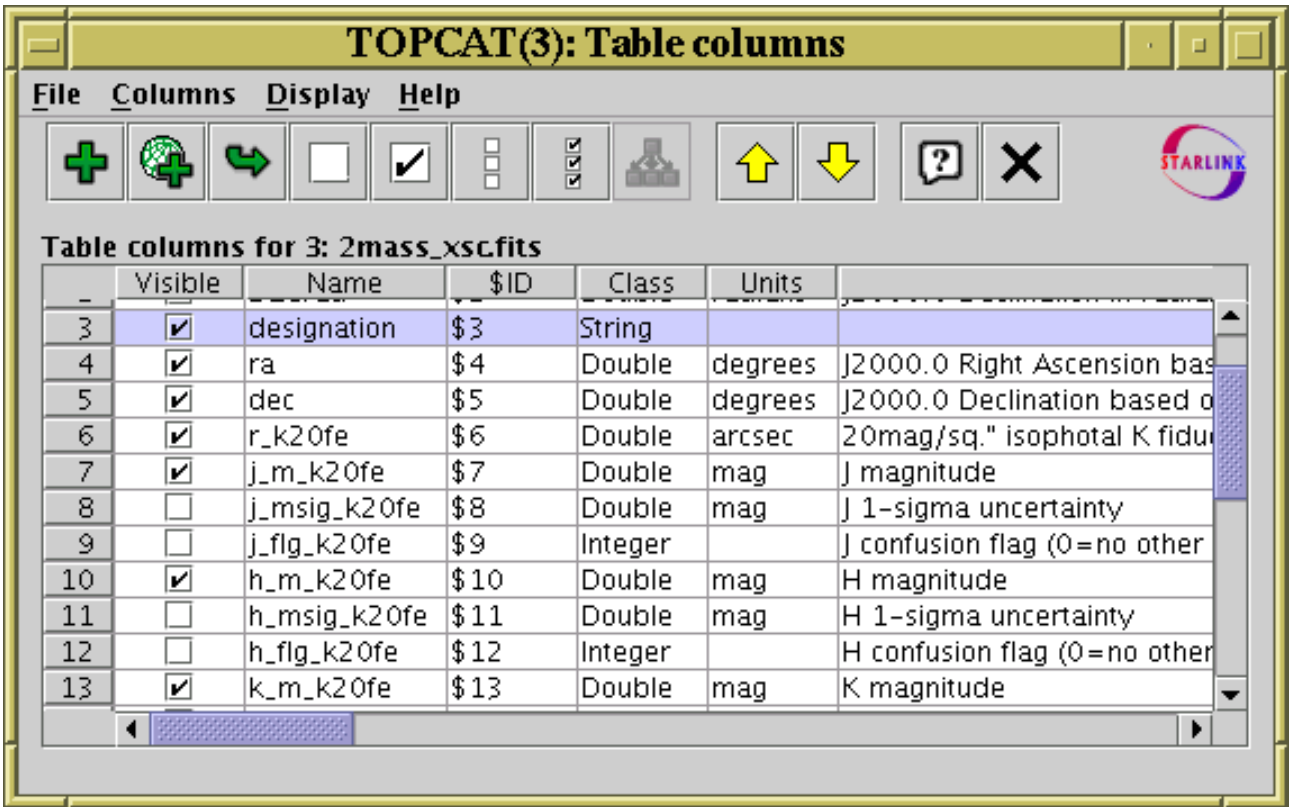

#### Remove Parameter

If one of the parameters displayed in the JTable in this window has been selected by clicking on its row, then clicking this button will remove it. You will be prompted before the removal takes place. Some parameters such as Row Count cannot be removed.

### A.3.3 Columns Window

**Columns Window**

The Columns Window displays a JTable giving all the information (metadata) known about each column in the table. You can display it using the **Column Info** (  ) button when the chosen table is selected in the Control Window's Table List.

The display may take a little bit of getting used to, since each *column* in the main data table is represented by a *row* in the JTable displayed here. The order and widths of the columns of JTable widget can be changed in the same way as those for the Data Window JTable, but this has no effect on the data.

The leftmost column, labelled "Visible", contains a checkbox in each row (one for each column of the data table). Initially, these are all ticked. By clicking on those boxes, you can toggle them between ticked and unticked. When unticked, the column in question will become hidden. The row can still be seen in this window, but the corresponding data column is no longer a part of the Apparent Table, so will not be seen in the Data Window or appear in exported versions of the table. You can tick/untick multiple columns at once by highlighting a set of rows by dragging the mouse over them and then using the **Hide Selected** (  ) or **Reveal Selected** (  ) toolbar buttons or menu items. If you want to hide or reveal all the columns in the table, use the **Hide All** (  ) or

**Reveal All** (  ) buttons.

Each column in the displayed JTable corresponds to one piece of information for each of the columns in the data table - column name, description, UCD etc. Tables of different types (e.g. ones read from different input formats) can have different categories of metadata. By default a metadata category is displayed in this JTable if at least one table column has a non-blank value for that metadata category, so for instance if no table columns have a defined UCD then the UCD column will not appear. Categories can be made to appear and disappear however by using the **Display** menu. The metadata items are as follows:

**Visible**

Indicates whether the column is part of the Apparent Table. If this box is not filled in, then for most purposes the column will be hidden from display. You can toggle visibility by clicking on this column.

**Name**

The name of the column.

**\$ID**

A unique and unchanging ID value for each column. These are useful in defining algebraic expressions (see Section 6) since they are guaranteed unique for each column. Although the column Name can be used as well, the Name may not be unique and may not have the correct form for use in an algebraic expression.

**Class**

The Java class of the items in that column. You don't have to know very much Java to understand these; they are Float or Double for floating point numbers; Byte, Short, Integer or Long for integer numbers, Boolean for a logical (true/false) flag, or String for a string of ASCII or Unicode characters. There are other possibilities, but these will cover most. The characters '[' after the name of the class indicates that each cell in the column holds an array of the indicated type.

**Shape**

Cells of a table can contain arrays as well as scalars. If the column contains an array type, this indicates the shape that it should be interpreted as. It gives the dimensions in column-major order. The last element may be a '\*' to indicate that the size of the array may be variable. For scalar columns, this item will be blank.

**Units**

The units in which quantities in this column are expressed.

**Expression**

The algebraic expression defining the values in this column. This will only be filled in if the column in question is a synthetic column which you have added, rather than one present in the data in their original loaded form.

**Description**

A textual description of the function of this column.

**UCD**

The UCD associated with this column, if one is specified. UCDs are Uniform Content Descriptors, and indicate the semantics of the values in this column.

**UCD Description**

If the string in the UCD column is the identifier of a known UCD, the standard description associated with that UCD is shown here.

There may be other items in the list specific to the table in question.

You can edit column names and some other entries in this JTable by double-clicking on them as usual.

The order in which the rows are presented is determined by the table's current Column Set (Section 3.3), so can be changed by dragging the column headers around in the Data Window.

The following buttons are available in the toolbar:

 **New Synthetic Column**

This pops up a Synthetic Column Window which allows you to define a new column in terms of the existing ones by writing an algebraic expression. The new column will be added by

default after the last selected column, or at the end if none is selected.

### Add Sky Coordinate Columns

This pops up a Sky Coordinates Window (Appendix A.7.8) which allows you to define a pair of new sky coordinate columns based on an existing pair of sky coordinate columns.

### Replace Column With Synthetic

If a single column is selected, then clicking this button will pop up a Synthetic Column dialogue (Appendix A.7.7) to replace the selected column with a new synthetic one. The dialogue is initialised with the same name, units etc as the selected column, and with an expression that evaluates to its value. You can alter any of these, and the new column will replace the old one, which will be hidden and renamed by appending a suffix like "\_old" to its name.

### Hide Selected Column(s)

If any of the columns are selected, then clicking this button will hide them, that is, remove them from the current Column Set. This has the same effect as deselecting all the checkboxes corresponding to these columns in the **Visible** column.

### Reveal Selected Column(s)

If any of the columns are selected, then clicking this button will make sure they are visible, that is, that they appear in the current Column Set. This has the same effect as selecting all the checkboxes corresponding to these columns in the **Visible** column.

### Hide All Columns

Clicking this button will hide all the columns in the table; the table will have no columns visible in it following this. If you just want to see a few columns, it may be convenient to use this button and then select a few visible ones individually to reveal.

### Reveal All Columns

Clicking this button will ensure that all the table's columns are visible (none are hidden).

### Explode Array Column

If a column is selected which has an array type, clicking this button will replace it with scalar-valued columns containing each of its elements. For instance if a column PMAG contains a 5-element vector of type `float[]` representing magnitudes in 5 different bands, then selecting it and hitting this button will hide PMAG and insert 5 new `float`-type columns PMAG\_1...PMAG\_5 in its place each containing one of the magnitudes.

### Sort Selected Up

If a single column is selected then the table's current Sort Order will be set to sort ascending on that column. Otherwise this action is not available.

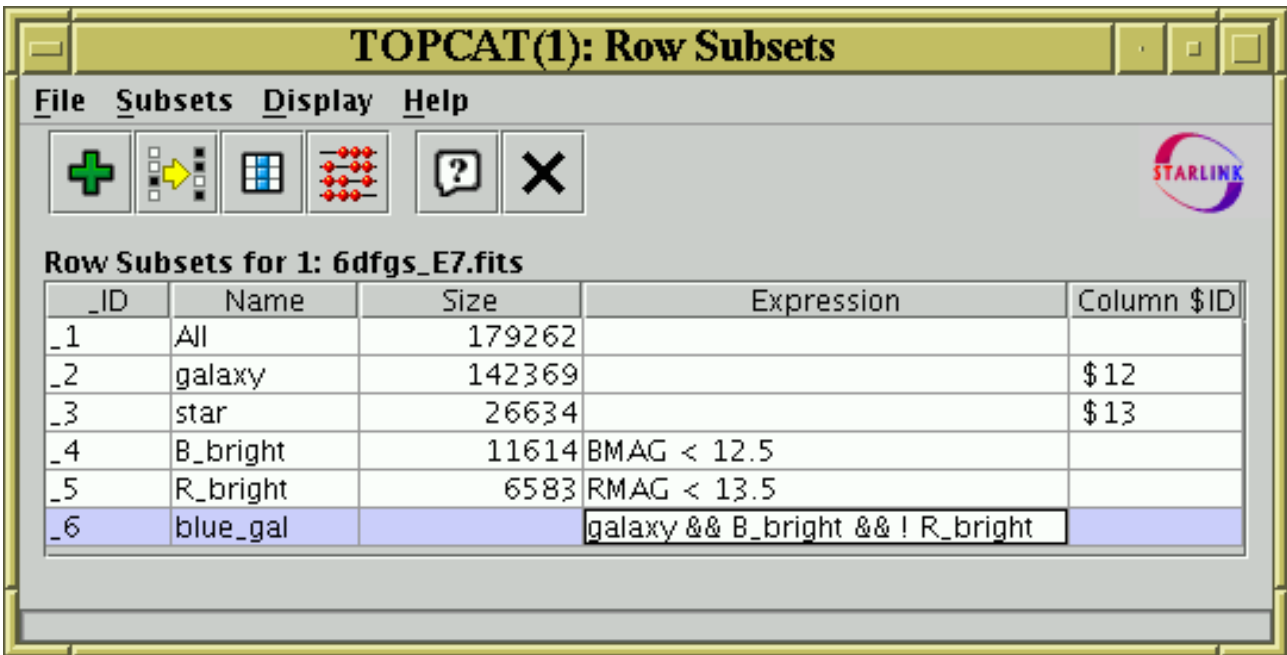

### Sort Selected Down

If a single column is selected then the table's current Sort Order will be set to sort descending on that column. Otherwise this action is not available.

Several of these actions operate on the currently selected column or columns. You can select columns by clicking on the corresponding row in the displayed JTable as usual. A side effect of selecting a single column is that the table view in the Data Window will be scrolled sideways so

that the selected column is visible in (approximately) the middle of the screen. This can be a boon if you are dealing with a table that contains a large number of columns.

### A.3.4 Subsets Window

#### Subsets Window

The Subsets Window displays the Row Subsets (Section 3.1) which have been defined. You can display it using the **Row Subsets** () button when the chosen table is selected in the Control

Window's Table List.

The subsets are displayed in a JTable widget with a row for each subset. The columns of the JTable are as follows:

#### \_ID

A unique and unchanging identifier for the subset, which consists of a "\_" character (underscore) followed by an integer. This can be used to refer to it in expressions (Section 6) for synthetic columns or other subsets.

**Note:** in previous versions of TOPCAT the hash sign ("#") was used instead of the underscore for this purpose; the hash sign no longer has this meaning.

#### **Name**

A name used to identify the subset. It is ideally, but not necessarily, unique.

#### **Size**

The number of rows in this subset. This column is initially blank, and is not guaranteed to remain correct if the subset definitions or the table data change, since counting may be an expensive process so it is not automatically done with every change. A count can be forced by using the **Count Subsets** () button described below.

#### **Expression**

If the subset has been defined by an algebraic expression, this will be here. It can be edited (double-click on the cell) to change the expression.

#### **Column \$ID**

If the subset has been defined by equivalence with a boolean-valued column, this will show the

\$ID of the column that it came from (see Appendix A.3.3).

Entries in the **Name** and **Expression** columns can be edited by double-clicking on them in the normal way.

The following toolbar buttons are available in this window:

 **New Subset**

Pops up the Algebraic Subset Window to allow you to define a new subset algebraically.

 **Invert Subset**

Creates a new subset which is the complement of the selected one. The new one will include all the rows which are excluded by the selected one (and vice versa). To use this action, first select a subset by clicking on its row in the JTable.

 **To Column**

If one of the rows in the JTable is selected, this will turn that subset into a new column. It will pop up the Synthetic Column Window, filled in appropriately to add a new boolean column to the table based on the selected subset. You can either accept it as is, or modify some of the fields. To use this action, first select a subset by clicking on its row in the JTable.

 **Count Subsets**

Counts how many rows are in each subset and displays this in the **Size** column. This forces a count or recount to fill in or update these values.

**A.3.5 Statistics Window**

**TOPCAT(6): Row statistics**

File Statistics Display Help

Row statistics for 6: qualfilter5rad.fits

Name	Mean	S.D.	Minimum	Maximum
area	427.97876	564.16803	43	16279

Subset for calculations: spiral

**Statistics Window**

The Statistics Window shows statistics for the values in each of the table's columns. You can display it using the **Column Statistics** ( $\Sigma$ ) button when the chosen table is selected in the

Control Window's Table List.

The calculated values are displayed in a JTable widget with a row for each column in the main table, and a column for each of a number of statistical quantities calculated on some or all of the values in the data table column corresponding to that grid row. The following columns are shown by default:

**Name**

The name of the column in the main table represented by this grid row.

**Mean**

The mean value of the good cells. For boolean columns, this is the proportion of good cells which are True.

**S.D.**

The standard deviation of the good cells.

**Minimum**

The minimum value. For numeric columns the meaning of this is quite obvious. For other columns, if an ordering can be reasonably defined on them, the 'smallest' value may be shown. For instance string values will show the entry which would be first alphabetically.

**Maximum**

As minimum, but shows the largest values.

**Good cells**

The number of non-blank cells.

Several additional items of statistical information are also calculated, but the columns displaying these are hidden by default to avoid clutter. You can reveal these by using the **Display** menu:

**Index**

The index of the column in the table, i.e. the order in which it is displayed.

**\$ID**

The unique identifier label for the column in the main table.

**Sum**

The sum of all the values in the column. For boolean columns this is a count of the number of True values in the column.

**Variance**

The variance of the good cells.

**Row of min.**

The index of the row in the main table at which the minimum value occurred.

**Row of max.**

The index of the row in the main table at which the maximum value occurred.

**Bad cells**

The number of blank cells; the sum of this value and the Good cells value will be the same for each column.

**Cardinality**

If the column contains a small number of distinct values then that number, the column's *cardinality* will be shown here. Cardinality is the number of distinct values which appear in that column. If the number of values represented is large (currently >50) or a large proportion of the non-bad values (currently >75%) then no value is shown.

The quantities displayed in this window are not necessarily those for the entire table; they are those for a particular Row Subset (Section 3.1). At the bottom of the window is the **Subset For Calculations** selector, which allows you to choose which subset you want the calculations to be done for. By clicking on this you can calculate the statistics for different subsets. When the window is first opened, or when it is invoked from a menu or the toolbar in the Control Window, the subset will correspond to the current row subset.

The toolbar contains the following extra button:

Once statistics have been calculated for a given subset they are cached and not normally recalculated again. Use this button if you want to force a recalculation because the data may have changed.

For a large table the calculations may take a short while. While they are being performed you can interact with the window as normal, but a progress bar is shown at the bottom of the window. If you initiate a new calculation (by pushing the Recalculate button or selecting a new subset) or close the window during a calculation, the superceded calculation will be stopped.

## A.4 Graphics Windows

TOPCAT has a number of windows for performing data visualisation of various kinds. These share various characteristics which are described in the first subsection below; the specific windows themselves are described in the subsequent subsections.

These visualisation windows are fairly sophisticated, and the plots can be exported to GIF or EPS files for later presentation (see Appendix A.4.1.4). However, at least at present, TOPCAT does not claim to be a full end-to-end system for generating publication quality graphics, and hence lacks facilities for detailed configuration of axis labelling, legend display, font control, data annotation and so on. You may well find that you can use it to generate publication quality graphics, but if you need features which are not currently provided you may find it best to use TOPCAT to investigate your data and decide exactly what data you want to present, and then export the data in a form which can be used by a more output-oriented package.

### A.4.1 Common Features

The various types of graphics windows have different characteristics to fulfil their different functions, but they share a common way of doing things. Each window contains a number of controls including toolbar buttons, menu items, column selectors and others. In general any change that you make to any of the controls will cause the plot to be redrawn to take account of that change. If this requires a read or re-read of the data, a progress bar at the bottom of the window may show this progressing - except for very large tables it is usually pretty fast.

Each of the graphics windows is displayed by clicking its toolbar button in the Control Window. If one of the tables in the list is selected at the time (the Current Table) the new plot window will initially be displayed showing data from some of its columns (usually the first few numeric columns) by way of illustration. You will usually want to change the controls so it displays the quantities you are interested in.

The following subsections describe some of the features which work the same for most or all of the graphics windows.

### A.4.1.1 Dataset Selectors

All the graphics windows provide one or more axes on which to plot - the histogram has 1, the 2d scatter and density plots have 2, the 3d scatter plot has 3 and the spherical plot has 2 or 3. In each case you select one or more dataset to plot on these axes, and select what plotting style to use for each set. A dataset is typically a number of columns from a table (the number matching the dimensionality of the plot) and a selection of row subsets associated with that table. You select this and the plotting style(s) using the panel at the bottom of each plot window. Here is dataset selector for the 2d scatter plot:

**Dataset selector from 2d scatter plot window**

The different parts of this control work as follows:

#### Data panel

The **Table** selector gives the identifier of the table (one of the ones loaded into TOPCAT) that the data comes from.

The **Axis** selectors (here **X Axis** and **Y Axis**) give the quantities to be plotted. If you click the little down arrow at the right of each selector you get a list of all the numeric columns in the chosen table, from which you can select one. If you click the little left and right arrows to the right of the selector it will cycle through all the columns in the table. However, if you prefer you can type in an expression to use here. This may be more convenient if there's a very long list of columns. However, what you type in doesn't have to be a column name, it can be an algebraic expression based on columns in the table. In the example, the X axis is a straight column name, and the Y axis is an expression. The expression language syntax is explained in Section 6.

The **Log** checkbox for each axis is used to select whether the scale should be logarithmic or linear.

The **Flip** checkbox for each axis is used to select whether the axis values increase in the conventional direction (left to right, bottom to top) or its opposite.

#### Row Subsets panel

This defines which row subsets for will be plotted in this window, and what plotting style should be used for them. In this case there are three defined subsets, All, galaxy and star. The checkboxes on the left indicate which ones will be displayed - here, only the latter two. Sets of points are generally plotted in the order they are selected for viewing; since points plotted afterwards can obscure ones plotted before ("underneath") this makes a difference. If you want to see a set of points without it being obscured by other ones in the plot, then deselect it and reselect it again (clicking twice in the corresponding checkbox), and this will ensure that its points are plotted on top.

The buttons to the right of each subset name show the symbol that is used in the plot to display the data from that subset, in this case a red cross and a blue circle. These are selected automatically when the subset is first selected for viewing (the initial default style set depends mainly on how many rows there are in the selected table - many rows gives small dots, few

gives big ones). However, you have a lot of freedom to configure how they appear. If you click the button with the symbol on it a dialogue will pop up which allows you to select colour, shape, transparency and so on, as well as things like whether fitted lines will be plotted for that subset. The options available differ according to the kind of plot, and are described along with the different graphics windows in the following subsections. The style window stays visible until you dismiss it, but if you click on another of the buttons in the Row Subsets panel its contents will change to allow you to select values for the corresponding subset. Most graphics windows have a **Marker Style** menu. This allows you to change all the styles in the plot at once to be members of a uniform set, for instance different coloured pixels, or black open shapes. If you select one of these it will overwrite the existing style selections, but they can be edited individually afterwards.

### Tabs

The example shows two tabs: **Main** and **A**; the Main one is currently visible. You can select a tab by clicking on its name. In each tab you select a table and a set of columns/expressions, and if they are all filled in it will contribute points (or bars, or whatever) to the plot. The Main dataset determines the initial values for the axis labels, but the data comes equally from all of them. The numerical values of the coordinates are the same for all the datasets, though their meanings might be different (for instance one dataset may be plotting V magnitude against ellipticity and another plotting B magnitude against ellipticity).

The + and - buttons at the left allow you to insert a new tab or remove an existing one respectively. You cannot remove the Main tab (which is why the - button is disabled in the figure).

### A.4.1.2 Axis Configuration and Zooming

In general terms the axes on which the graphics are plotted are defined by the datasets you have selected. The axis labels are set from the column names or expressions chosen for the **Main** dataset, and the ranges are determined so that all the data from the chosen datasets can be seen. However, these things can be adjusted manually.

The following features are available directly from the window for configuring axis range:

#### X-Y Zoom

In some of the windows (2d scatter plot, histogram and density map), you can change both axis ranges by zooming in or out with the mouse on the plot surface itself. To zoom in, place the mouse at the top left of the region you want to examine, press the button, drag it to the bottom right corner, and release the button. To zoom out, drag up and left instead. A box is drawn as you drag so you can see what you're doing.

#### Axis Zoom

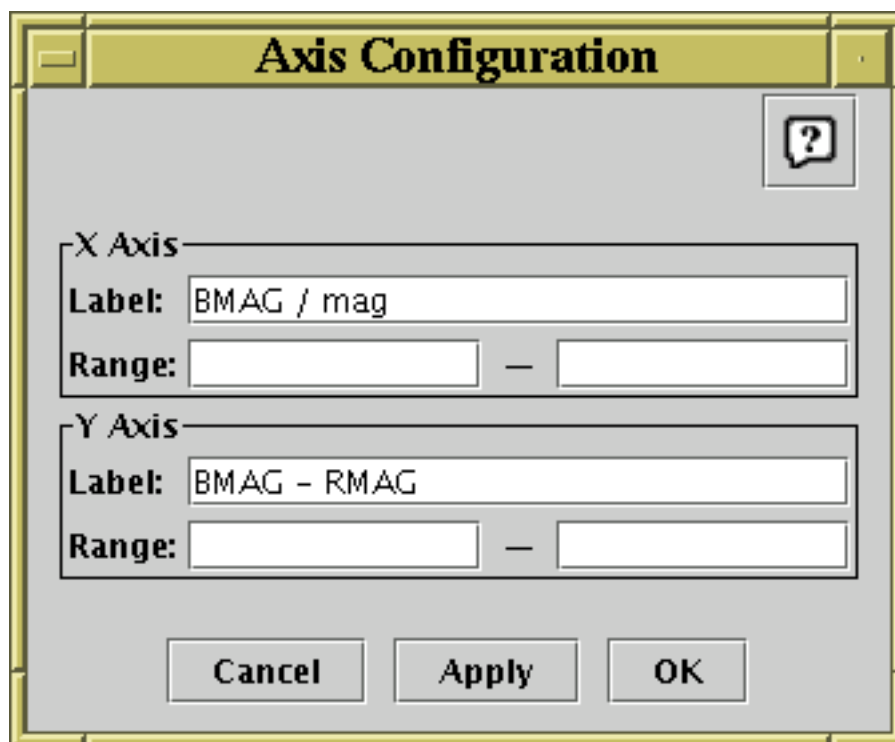

In some of the windows (2d scatter plot, histogram, density map, stacked lines) you can modify the range on each axis independently by dragging the mouse over where the axis is drawn. The 'active region' for dragging is just below the X axis and just to the left of the Y axis, in the region where the numeric and text labels are written. When the pointer is in one of these regions, the mouse cursor symbol changes to indicate that zooming can be done. As for the X-Y Zoom, drag left-to-right or up-to-down to zoom in and right-to-left or down-to-up to zoom out.

#### Rescale

If you find you're zoomed to a region you don't want to be in, you can use the Rescale toolbar button to return to the default scale (full coverage). Some windows may have per-axis rescale buttons too (, ).

For more control over axis range and labelling, use the **Configure Axes**  toolbar button, which will pop up a dialogue like the following:

#### Axis Configuration Dialogue for 2-d axes

You can fill in these values as follows:

##### Label

For each axis the label box contains the text used to annotate the axis in the plot. By default this is the same as the text in the **Main** dataset column selector (usually a column name), followed by the units if known. However, you can change it by typing whatever text you like.

##### Range

The range boxes allow you to specify the lower and upper limits of each axis. By default these are blank, meaning that the plot will size its axes so that all the data can be seen. However, if you fill in one or both of the boxes with a suitable numeric value, the lower/upper bound will be fixed at that. Note that the lower bound (left box) must be numerically less than the upper bound (right box).

Both values are reset if the plot's axis is changed (a new column or expression is selected for the Main dataset), or if the range is reset in some other way (e.g. by zooming).

#### A.4.1.3 Defining Subsets by Region

When quantities are plotted in one of the graphics windows it becomes easy to see groupings of the data which may not otherwise be apparent; a cluster of (X,Y) points representing a group of rows may correspond to a physically meaningful grouping of objects which you would like to treat separately elsewhere in the program, for instance by calculating statistics on just these rows, writing them out to a new table, or plotting them in a different colour on graphs with different coordinates. This is easily accomplished by creating a new Row Subset containing the grouped points, and the graphics windows provide ways of doing this.

In the 2-d plots (Histogram 2d Scatter plot and Density map) you can set the axis ranges (either

manually or by zooming with the mouse - see Appendix A.4.1.2) so that only the points you want to identify are visible, and then click the **New Subset From Visible** (,  or ) toolbar

button. This defines a subset consisting of all the points that are visible on the current plot. This is only useful if the group you are interested in corresponds to a rectangular region in the plotting space.

A more flexible way is to draw a region or regions on the plot which identify the points you are interested in. To do this, hit the **Draw Subset Region** () toolbar button. Having done this, you

can drag the mouse around on the plot (keep the left mouse button down while you move) to encircle the points that you're interested in. As you do so, a translucent grey blob will be left behind - anything inside the blob will end up in the subset. You can draw one or many blobs, which may be overlapping or not. If you make a mistake while drawing a sequence of blobs, you can click the right mouse button, and the most recently added blob will disappear. When you're in this region-drawing mode, you can't zoom or resize the window or change the characteristics of the plot, and the **Draw Subset Region** button appears with a tick over it () to remind you you're in it.

Here's what the plot looks like while you're drawing:

### Region-Drawing Mode

When you're happy with the region you've defined, click the  toolbar button again.

In either case, when you have indicated that you want to define a new row subset, a dialogue box will pop up to ask you its name. As described in Section 3.1.1, it's a good idea to use a name which you haven't used before, and which is just composed of letters, numbers and underscores. When you enter a name and hit the **OK** button, the new subset will be created and the points in it will be shown straight away on the plot using a new symbol. As usual, you can toggle whether the points in this subset are displayed using the **Row Subsets** box at the bottom of the Plot Window.

#### A.4.1.4 Exporting Graphics

All the graphics windows have the following export options:

**Export as GIF**

**Export as Encapsulated PostScript**

These can be used to export the currently visible plot to an external graphics format for later use.

Exporting to GIF is pretty straightforward - what you see is what you get.

When exporting to Encapsulated PostScript (EPS) there are a few things to consider:

### **Positional Quantisation**

The output file will render text, lines and markers properly, with smooth edges rather than steps where pixel boundaries would be on the screen. However, the *positional* resolution is the same as it would be on the screen, so if you have a 400-pixel high plot for instance, there are only 400 possible Y coordinates at which a marker can be plotted. In general this is not obvious by looking at the output plot, but you may find it helpful to increase the size of the plot on the screen by resizing the window before performing an export to EPS. This reduces the effect of the positional quantisation, but note it will also have the effect of making the text labels proportionally smaller to the graphics.

### **Transparency**

For technical reasons transparent markers cannot easily be rendered when a plot is exported to PostScript. In some cases the plot is done using a bitmap in the PostScript output to permit transparency and in some cases the points are just plotted opaque. Try it and see; if the points come out opaque instead of transparent you may need to export to GIF instead. Better workarounds may be provided in future releases.

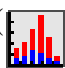

### **File Size**

In some cases (2D and 3D scatter plots with many thousands of points) output EPS files can get extremely large; the size scales with the number of points drawn, currently with a factor of a few hundred bytes per point. In some cases you can work round this by plotting some points as transparent so that the plot is rendered as a bitmap (see the discussion of transparency above) which scales as the number of pixels rather than the number of points. There may be some improvement to this in future releases.

## **A.4.2 Histogram**

### Histogram Window

The histogram window lets you plot histograms of one or more columns or derived quantities. You can display it using the **Histogram** () button in the Control Window's toolbar.

You select the quantity or quantities to plot using the dataset selector (Appendix A.4.1.1) at the bottom of the window. You can configure the axes, including zooming in and out, with the mouse or manually as described in Appendix A.4.1.2.

The **Bin Placement** box below the main plot controls where the bars are drawn. Select the horizontal range of each bar using the **Width** entry box - either type in the value you want or use the tiny up/down arrows at the right to increase/decrease the bin size. The **Offset** checkbox on the left determines where the zero point on the horizontal axis falls in relation to the bins; if the box is checked then zero is in the centre of a bin, and if it's unchecked then zero is on a bin boundary.

The following buttons are available on the toolbar:

**Export as EPS**

Pops up a dialogue which will write the current plot as an EPS file.

### Export as GIF

Pops up a dialogue which will output the current plot to a GIF file. The output file is just the same as the plotted image that you see. Resize the plotting window before the export to control the size of the output GIF.

### Rescale

Rescales the axes so that the width and height are sufficient to accommodate all the non-zero bars in the histogram for all the currently selected datasets. By default the plot will be scaled like this, but it may have changed because of changes in the subset selection or from zooming in or out.

### Rescale X

Rescales the horizontal axis to accommodate all the currently plotted bars. The vertical axis scaling is not changed.

### Rescale Y

Rescales the vertical axis to accommodate all the currently plotted bars. The horizontal axis scaling is not changed.

### Configure Axes

Pops up a dialogue to allow manual configuration of axis ranges and labels - see Appendix A.4.1.2.

### Grid

Toggles whether a grid is drawn over the plotting surface or not.

### Cumulative Plot

Toggles whether the histogram should be normal or cumulative. Normally the height of each bar is determined by counting the number of points which fall into the range on the X axis that it covers. For a cumulative plot, the height is determined by counting all the points between negative infinity and the upper bound of the range on the X axis that it covers.

### Log Y Axis

Toggles whether the Y axis is scaled logarithmically or not.

### Replot

Redraws the current plot. It is usually not necessary to use this button, since if you change any of the plot characteristics with the controls in this window the plot will be redrawn automatically. However if you have changed the data, e.g. by editing cells in the Data Window, the plot is not automatically redrawn (since this is potentially an expensive operation and you may not require it). Clicking this button redraws the plot taking account of any changes to the table data.

### Subset From Visible

Defines a new **Row Subset** consisting of only the data in the bars which are visible in the current plot. See Appendix A.4.1.3 for more explanation.

You have considerable freedom to configure how the bars are drawn; controlling this is described in

the following subsection.

#### A.4.2.1 Histogram Style Editor

The bins in a histogram can be represented in many different ways. A representation of how a bar will be displayed is shown on a button to the right of the name of each visible subset, at the bottom right of the histogram window. If you click this button the following dialogue will pop up which enables you to change the appearance.

#### Style editor dialogue for histogram bars

The **Legend** box defines how the marker will be displayed in the legend which appears alongside the plot:

##### Icon

Displays the icon which will be shown to identify the points in the selected set. Its appearance depends on the selections you make in the rest of this dialogue window.

##### Label

Gives the name written in the legend to label the subset. By default this is derived from the Row Subset's name and, if it's not part of the main dataset, the name of the dataset's tab. You can type in a new value to change what is written in the legend.

The **Bars** panel describes the form of the bars to be plotted for each data set.

##### Colour

Selects the colour for the bar or line which will represent this set.

##### Bar Form

Selects the style of bar which will be plotted. Available styles are filled rectangles, open rectangles, stepped lines and spikes.

**Bar Placement**

Selects where each bar will be placed on the X axis within the ordinate region which it represents. There are currently two options: **Over** means that it covers the whole of its range, and **Adjacent** means that it covers only a proportion of its range, so that multiple datasets plotted on the same graph don't obscure each other (if 2 sets are plotted, the first one will take the left half and the second will take the right half of each bin region, and so on). In the case that there is only a single data set plotted, it doesn't matter which of these is chosen.

**Line Thickness**

Determines the thickness in pixels of any lines which are drawn. Only applies to those **Bar Forms** which use lines rather than solid blocks.

**Dash**

Determines the dash style (solid, dotted, dashed or dot-dashed) for any lines which are drawn. Only applies to those **Bar Forms** which use lines rather than solid blocks.

Any changes you make in this window are reflected in the plot straight away. If you click the **OK** button at the bottom, the window will disappear and the changes remain. If you click **Cancel** the window will disappear and any changes you made will be discarded.

You can also change all the plotting styles at once by using the **Bar Style** menu in the histogram window. Here you can select a standard group of styles (e.g. all filled adjacent bars with different colours) for the plotted sets.

**A.4.3 2D Plot**

## Plot Window

The plot window allows you to do 2-dimensional scatter plots of one or more pair of table columns (or derived quantities). You can display it using the **Plot** () button in the Control Window's toolbar.

On the plotting surface a marker is plotted for each row in the selected dataset(s) at a position determined by the values in the table columns selected to provide the X and Y values. A marker will only be plotted if both the X and Y values are not blank. Select the quantities to plot and the plotting symbols with the dataset selector (Appendix A.4.1.1) at the bottom. You can configure the axes, including zooming in and out, with the mouse or manually as described in Appendix A.4.1.2.

Clicking on any of the plotted points will **activate** it - see Section 7.

The following buttons are available on the toolbar:

**Export as EPS**

Pops up a dialogue which will write the current plot as an EPS file. In general this is a faithful and high quality rendering of what is displayed in the plot window. However, if plotting is being done using the transparent markers, it won't come out right since transparency cannot be represented in PostScript; the markers will be rendered as if they were opaque. Currently, if there are many points being plotted, this can result in a rather large output file.

**Export as GIF**

Pops up a dialogue which will output the current plot to a GIF file. The output file is just the same as the plotted image that you see. Resize the plotting window before the export to control the size of the output GIF.

**Rescale**

Rescales the axes of the current plot so that it contains all the data points in the currently selected subsets. By default the plot will be scaled like this, but it may have changed because of changes in the subset selection or from zooming in or out.

**Configure Axes**

Pops up a dialogue to allow manual configuration of axis ranges and labels - see Appendix A.4.1.2.

**Grid**

Toggles whether a grid is drawn over the plotting surface or not.

**Replot**

Redraws the current plot. It is usually not necessary to use this button, since if you change any of the plot characteristics with the controls in this window the plot will be redrawn automatically. However if you have changed the data, e.g. by editing cells in the Data Window, the plot is not automatically redrawn (since this is potentially an expensive operation and you may not require it). Clicking this button redraws the plot taking account of any changes to the table data.

**Draw Subset Region**

Allows you to draw a region on the screen defining a new Row Subset. When you have finished drawing it, click this button again to indicate you're done. See Appendix A.4.1.3 for more details.

**Subset From Visible**

Defines a new **Row Subset** consisting of only the points which are currently visible on the plotting surface. See Appendix A.4.1.3 for more explanation.

You have considerable freedom to configure how the points are plotted including symbol shapes, colours, transparency and whether fitted or joined are plotted; this is described in the following subsection.

**A.4.3.1 Plot Style Editor**

When plotting points in a scatter plot there are many different ways that each point can be displayed. By default, TOPCAT chooses a set of markers on the basis of how many points there are in the table and uses a different one for each plotted set. The marker for each set is displayed in a

button to the right of its name in the dataset selector panel at the bottom of the plot window. If you click this button the following dialogue will pop up which enables you to change the appearance.

Style editor dialogue for 2d scatter plot

The **Legend** box defines how the marker will be displayed in the legend which appears alongside the plot:

#### Icon

Displays the icon which will be shown to identify the points in the selected set. Its appearance depends on the selections you make in the rest of this dialogue window.

#### Label

Gives the name written in the legend to label the subset. By default this is derived from the Row Subset's name and, if it's not part of the main dataset, the name of the dataset's tab. You can type in a new value to change what is written in the legend.

The **Marker** box defines how the markers plotted for each data point will appear:

#### Shape

Choose from a variety of shapes such as open or filled circles, squares, crosses etc.

#### Size

Choose the size of the marker; the value given is approximate radius in pixels. If a size of zero is chosen, then the shape doesn't matter, the points will be plotted as single pixels.

**Colour**

Choose the colour in which the markers, and any line if one is drawn, will be plotted.

**Transparency**

Choose transparency of the plotted symbols. The scale on the slider is logarithmic, with 1 at the left hand end. The actual value chosen is an integer written at the right of the slider. This number gives the number of markers for this set which need to be plotted in the same position to result in fully opaque pixels - any fewer and the background, or other markers plotted underneath, will show through to some extent. Setting this to some value greater than 1 is very useful if you have a very large number of points being plotted (especially if it's comparable with the number of the pixels on the screen), since it enables to you distinguish regions where there are lots of points on top of each other from those where there are only a few.

**Hide Markers**

This check box is only enabled if a line is being plotted; it allows the markers to be invisible, so that only the line is seen.

The **Line** box determines if any lines are drawn associated with the current set and if so what their appearance will be.

**Thickness**

Selects the line thickness in pixels.

**Dash**

Selects a dash pattern (solid, dotted, dashed or dot-dashed) for the line.

**Type**

The other radio buttons determine what kind of line, if any, will be plotted for these points. There are three options:

**None**

No line is drawn - this is the default.

**Dot to Dot**

A straight line segment is drawn between each of the points. If the points effectively form an ordered set of samples of a function, this will result in a more-or-less smooth drawing of that function on the plot. Note that the lines are drawn in the order that the points appear in the basic table, and if this doesn't match the 'ordinate' order the result will be a mess. Really, the drawing order ought to be the table's current sort order - that it is not is a misfeature which may be corrected at some point. Note also that if you try this with a huge table you're likely to get a result which (a) is messy and (b) takes a very long time to draw.

**Linear Correlation**

If you select this option then a linear regression line will be plotted. The correlation coefficients will also be displayed to the right of the radio button (you may need to resize the window to see them all). The values cited are  $m$  (gradient),  $c$  (intercept) and  $r$  (product moment correlation coefficient).

**Note** that for both the plotted line and the quoted coefficients the data is taken only from the points which are currently visible - that means that if you've zoomed the axes to exclude some of the data points, they will not be contributing to the calculated statistics.

Any changes you make in this window are reflected in the plot straight away. If you click the **OK** button at the bottom, the window will disappear and the changes remain. If you click **Cancel** the

window will disappear and any changes you made will be discarded.

You can also change all the plotting styles at once by using the **Marker Style** menu in the plot window. Here you can select a standard group of styles (e.g. all open 2-pixel markers with different colours and shapes) for the plotted sets.

### A.4.4 Stacked Line Plot

### Stacked Lines Window

The stacked line plot window allows you to plot one or more ordinate (Y) quantities against a monotonic abscissa (X) quantity. For clarity, the different plots are displayed on vertically displaced graphs which share the same X axis. You can display this window using the **Lines**  button in

the Control Window's toolbar.

The display initially holds a single X-Y graph, usually with lines connecting adjacent points. The points will be reordered before drawing if necessary so that the line is displayed as a function of X, rather than of an invisible third independent variable (in the Scatter Plot this isn't done which can lead to lines being scribbled all over the plot). If one of the columns in the table appears to represent a time value, this will be selected as the default X axis. Otherwise, the 'magic' **index** variable will be used, which represents the row number. Of course, these can be changed from their default values using the selectors in the usual way.

To add a new graph with a different Y axis, use the **Add Dataset** () button in the dataset selectors panel at the bottom of the window. This has a slightly different effect from what it does in the other plot windows, in that it inserts a new plotting region with its own Y axis at the top of the plot on which the specified data is drawn, rather than only causing a new set of points to be plotted on the existing plot region. Thus all the datasets appear in their own graphs with their own Y axes (though if you have multiple row subsets plotted for the same dataset they will appear on the same part of the plot as usual). To remove one of the graphs, select its tab and use the **Remove Dataset** () button as usual.

**Zooming** can only be done on one axis at a time rather than dragging out an X-Y region on the plot surface, since there isn't a single Y axis to zoom on. To zoom the X axis in/out, position the mouse just below the X axis at the bottom of the plot and drag right/left. To zoom one of the Y axes in or out, position the mouse just to the left of the Y axis you're interested in and drag down/up. To set the ranges manually, use the **Configure Axes** () button as usual, but note that there is one

label/range setting box for each of the Y axes. These things work largely as described in Appendix A.4.1.2, as long as you bear in mind that the range of each of the Y axes is treated independently of the others.

Clicking on any of the points will **activate** it - see Section 7.

The following buttons are available on the toolbar:

#### **Export as EPS**

Pops up a dialogue which will write the current plot as an EPS file.

#### **Export as GIF**

Pops up a dialogue which will output the current plot to a GIF file. The output file is just the same as the plotted image that you see. Resize the plotting window before the export to control the size of the output GIF.

#### **Rescale**

Rescales all the plots so that all points in the plotted datasets can be seen. The X axis and all the Y axes are rescaled to fit the data.

#### **Rescale X Axis**

Rescales the X axis only. The X axis is rescaled to cover the lowest and highest values on any of the plotted datasets, but the Y ranges are left as they are.

#### **Rescale Y Axes**

Rescales the Y axes only. Each of the plotted Y axes are independently rescaled so that they

cover the lowest and highest values within the currently visible X range.

### Configure Axes

Pops up a dialogue to allow manual configuration of the range and label for the X axis and each of the Y axes - see Appendix A.4.1.2.

### Full Grid

Toggles whether X and Y grid lines are drawn over the plots or not. If this is selected, the single  $y=0$  grid line (see next item) will automatically be deselected.

### y=0 Grid Lines

Toggles whether a single horizontal line at  $y=0$  is drawn. If this is selected, the full grid (see previous item) will automatically be deselected.

Redraws the current plot. It is usually not necessary to use this button, since if you change any of the plot characteristics with the controls in this window the plot will be redrawn automatically. However if you have changed the data, e.g. by editing cells in the Data Window, the plot is not automatically redrawn (since this is potentially an expensive operation and you may not require it). Clicking this button redraws the plot taking account of any changes to the table data.

### Antialias

Toggles whether lines are drawn with antialiasing. Antialiasing means smoothing lines so that they appear less pixelised, and generally improves the aesthetic appearance of the plot, but in some circumstances it might look better not antialiased. The state of this button does not affect images exported to postscript.

### Subset From X Range

Defines a new **Row Subset** in each of the plotted tables consisting of only the points in the currently visible range on the horizontal axis. Points will be included even if they are outside the current ranges of the Y axes.

### Show Vertical Crosshair

Toggles whether a vertical line follows the mouse when it is positioned over the plot. This can be useful to compare features in different graphs at the same X coordinate position.

You can determine how the data are plotted using lines and/or markers as described in the following subsection.

#### A.4.4.1 Lines Style Editor

The default plotting style for the stacked lines plot is a simple black line for each graph. Since the plots typically do not overlap each other, this is in many cases suitable as it stands. However, you can configure the plotting style so that the points are plotted with markers as well as or instead of lines, and change the colours, marker shapes, line styles etc. The style for each row subset is displayed in a button to the right of its name in the bottom right of the plotting window. If you click this button the following dialogue will pop up which entables you to configure the plotting style.

### Stacked Line Plot Style Editor

The **Display** box defines how the markers plotted for each data point will appear:

#### Colour

Choose the colour in which the lines and/or markers will be plotted.

#### Line/Markers

Select from the radio buttons whether you want just lines between the data points, or markers at each point, or both.

The **Line** box defines how the lines joining the points will look. These controls will only be active if the Display selection is **Line** or **Both**.

#### Thickness

Determines line thickness.

#### Dash

Determines line dash pattern.

The **Markers** box defines how markers at the data points will look. These controls will only be active if the Display selection is **Markers** or **Both**.

#### Size

Determines the size of the markers in pixels. If a size of zero is chosen then the shape doesn't matter, the points will be plotted as single pixels.

#### Shape

Determines the shape of the markers from a selection such as open or filled circles, squares, crosses etc.

Any changes you make in this window are reflected in the plot straight away. If you click the **OK** button at the bottom, the window will disappear and the changes remain. If you click **Cancel** the window will disappear and any changes you made will be discarded.

You can also change all the plotting styles at once by using the **Line Style** menu in the stacked lines plot window. Here you can select a standard group of styles (e.g. dashed lines, coloured lines) for the plotted sets.

#### **A.4.5 3D Plot**

### 3D scatter plot window

The 3D plot window draws 3-dimensional scatter plots of one or more triples of table columns (or derived quantities) on Cartesian axes. You can display it using the **3D**  button in the Control

Window's toolbar.

On the display a marker is plotted for each row in the selected dataset(s) at a position determined by the values in the table columns selected to provide the X, Y and Z values. A marker will only be plotted if none of the X, Y and Z values are blank. Select the quantities to plot and the plotting symbols with the dataset selector (Appendix A.4.1.1) at the bottom.

The 3D space can be rotated by dragging the mouse around on the surface - it will rotate around the point in the centre of the plotted cube. The axis labels try to display themselves the right way up and in a way which is readable from the viewing point if possible, which means they move around while the rotation is happening. By default the points are rendered as though the 3D space is filled with a 'fog', so that more distant points appear more washed out - this provides a visual cue which can help to distinguish the depth of plotted points. However, you can turn this off if you want. You can't zoom in and out of the plot using the mouse, but you can use the Axis Configuration Dialogue (Appendix A.4.1.2) to set axis ranges (and labels) manually. If there are many points, then you may find that they're not all plotted while a drag-to-rotate gesture is in progress. This is done to cut down on rendering time so that GUI response stays fast. When the drag is finished (i.e. when you release the mouse button) all the points will come back again.

Clicking on any of the plotted points will **activate** it - see Section 7.

The following buttons are available on the toolbar:

#### **Export as EPS**

Pops up a dialogue which will write the current plot as an EPS file. In general this is a faithful and high quality rendering of what is displayed in the plot window. However, if plotting is being done using the transparent markers, it won't come out right since transparency cannot be represented in PostScript; the markers will be rendered as if they were opaque. Currently, if there are many points being plotted, this can result in a rather large output file.

#### **Export as GIF**

Pops up a dialogue which will output the current plot to a GIF file. The output file is just the same as the plotted image that you see. Resize the plotting window before the export to control the size of the output GIF.

#### **Rescale**

Rescales the axes of the current plot so that it contains all the data points in the currently selected subsets. By default the plot will be scaled like this, but it may have changed because of changes in the subset selection.

#### **Reorient**

Reorients the axes of the current plot to their default position. This can be useful if you've lost track of where you've rotated the plot to with the mouse.

#### **Grid**

Toggles whether the axis lines are drawn or not.

#### **Fog**

Toggles whether rendering is done as if the space is filled with fog. If this option is selected, distant points will appear more washed out than near ones.

#### **Replot**

Redraws the current plot. It is usually not necessary to use this button, since if you change any of the plot characteristics with the controls in this window the plot will be redrawn automatically. However if you have changed the data, e.g. by editing cells in the Data Window, the plot is not automatically redrawn (since this is potentially an expensive operation and you may not require it). Clicking this button redraws the plot taking account of any changes to the table data.

### Draw Subset Region

Allows you to draw a region on the screen defining a new Row Subset. When you have finished drawing it, click this button again to indicate you're done. The subset will include points at all depths in the viewing direction which fall in the region you have drawn. See Appendix A.4.1.3 for more details.

The following additional item is available as a menu item only:

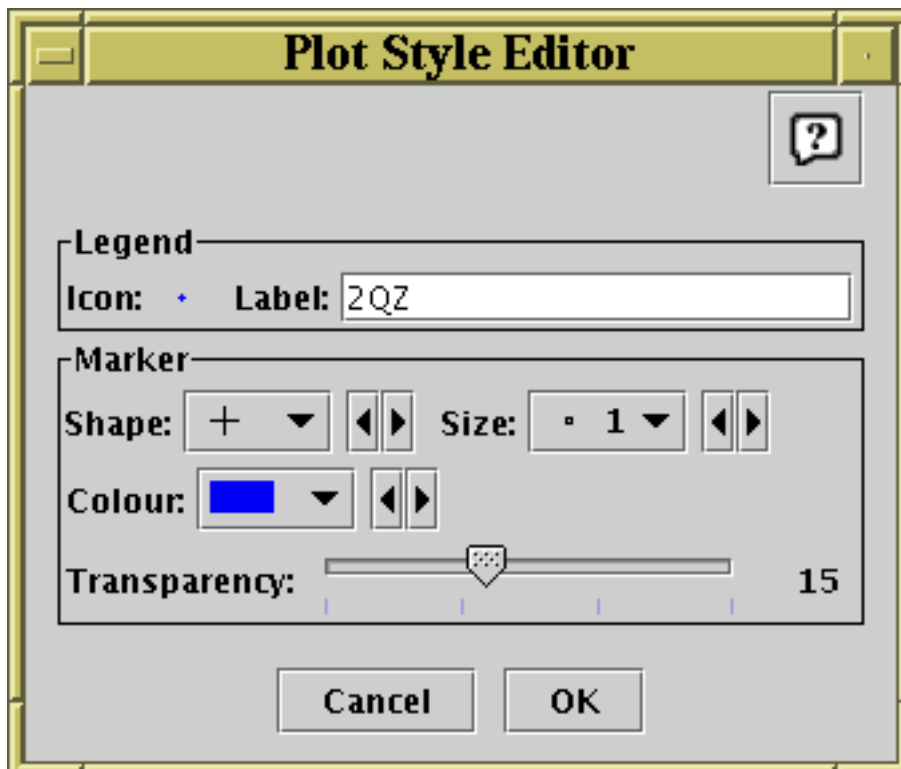

### Antialias

Toggles whether the axes and their annotations are drawn antialiased. Antialiased lines are smoother and generally look more pleasing, especially for text at a sharp angle, but it can slow the rendering down a bit.

You have considerable freedom to configure how the points are plotted including symbol shapes, colours and transparency; this is described in the following subsection.

#### A.4.5.1 3D Plot Style Editor

When plotting points in a 3D plot there are many different ways that each point can be displayed. By default, TOPCAT chooses a set of markers on the basis of how many points there are in the table and uses a different one for each plotted set. The marker for each set is displayed in a button to the right of its name in the dataset selector panel at the bottom of the plot window. If you click this button the following dialogue will pop up which enables you to change the appearance.

## Style editor dialogue for 3d plots

The **Legend** box defines how the marker will be displayed in the legend which appears alongside the plot:

### Icon

Displays the icon which will be shown to identify the points in the selected set. Its appearance depends on the selections you make in the rest of this dialogue window.

### Label

Gives the name written in the legend to label the subset. By default this is derived from the Row Subset's name and, if it's not part of the main dataset, the name of the dataset's tab. You can type in a new value to change what is written in the legend.

The **Marker** box defines how the markers plotted for each data point will appear:

### Shape

Choose from a variety of shapes such as open or filled circles, squares, crosses etc.

### Size

Choose the size of the marker; the value given is approximate radius in pixels. If a size of zero is chosen, then the shape doesn't matter, the points will be plotted as single pixels.

### Colour

Choose the colour in which the markers will be plotted.

### Transparency

Choose transparency of the plotted symbols. The scale on the slider is logarithmic, with 1 at the left hand end. The actual value chosen is an integer written at the right of the slider. This number gives the number of markers for this set which need to be plotted in the same position to result in fully opaque pixels - any fewer and the background, or other markers plotted underneath, will show through to some extent. Setting this to some value greater than 1 is very useful if you have a very large number of points being plotted (especially if it's comparable with the number of the pixels on the screen), since it enables you to distinguish regions where there are lots of points on top of each other from those where there are only a few. If a finite transparency is set, you may find it useful to turn off fogging (see above).

Any changes you make in this window are reflected in the plot straight away. If you click the **OK** button at the bottom, the window will disappear and the changes remain. If you click **Cancel** the window will disappear and any changes you made will be discarded.

You can also change all the plotting styles at once by using the **Marker Style** menu in the plot window. Here you can select a standard group of styles (e.g. all open 2-pixel markers with different colours and shapes) for the plotted sets.

## A.4.6 Spherical Plot

### Spherical plot window

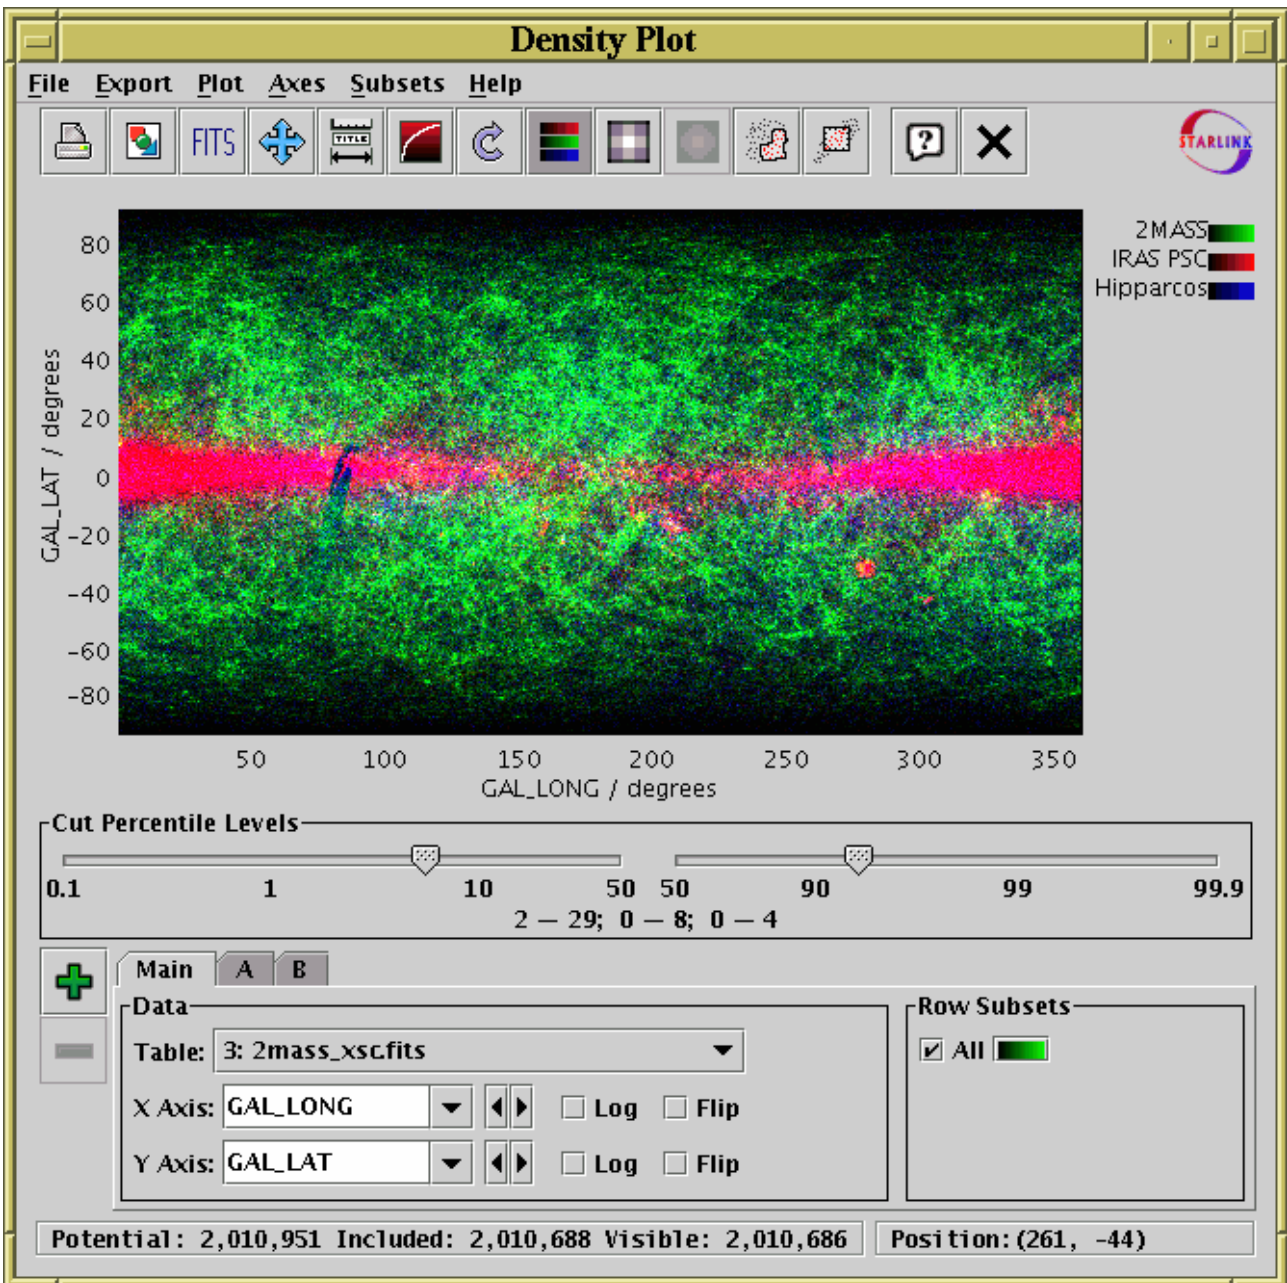

The spherical plot window draws 3-dimensional scatter plots of datasets from one or more tables on spherical polar axes, so it's suitable for displaying the position of coordinates on the sky or some other spherical coordinate system, such as the surface of a planet or the sun. You can display it

using the **Sphere** (  ) button in the Control Window's toolbar.

In most respects this window works like the 3D Plot window, but it uses spherical polar axes rather than Cartesian ones. You have to fill in the dataset selector (Appendix A.4.1.1) at the bottom with longitude- and latitude-type coordinates from the table. Selectors are included to indicate the units of those coordinates. If TOPCAT can locate columns in the table which appear to represent Right Ascension and Declination, these will be filled in automatically. If only these two are filled in, then the points will be plotted on the surface of the unit sphere - this is suitable if you just want to inspect the positions of a set of objects in the sky. You can optionally fill in the **Radius** selector as well. If you do this, then points will be plotted on the interior of the sphere, at a distance from the centre given by the value of the radial coordinate.

Rotation, subset creation, fogging, marker customisation and toolbar actions are all as for the Cartesian 3D plot window - see Appendix A.4.5.

### A.4.7 Density Map

## Density map window

The density map window plots a 2-dimensional density map of one or more pairs of table columns (or derived quantities); the colour of each pixel displayed is determined by the number of points in the data set which fall within its bounds. Another way to think of this is as a histogram on a 2-dimensional grid, rather than a 1-dimensional one as in the Histogram Window. If multiple datasets are being plotted, pixel colours can either be at a single brightness level derived from total number of points, or a combination of up to three independent (red, green, blue) colour channels from different datasets.

Density maps are suitable when you have a very large number of points to plot, since in this case it's important to be able to see not just whether there is a point at a given pixel, but how many points fall on that pixel. To a large extent, the transparency features of the other 2d and 3d plotting windows address this issue, but the density map gives you a bit more control. It can also export the result as a FITS image, which can then be processed or viewed using image-specific software such as GAIA or Aladin.

You can configure the axes, including zooming in and out, with the mouse or manually as described in Appendix A.4.1.2.

The **Cut Percentile Levels** panel below the plot controls how the number of counts in each pixel maps to a brightness. There are two sliders, one for the lower bound and one for the upper bound. They are labelled (logarithmically) with percentile values. If the upper one is set to 90, it means that any pixel above the 90th percentile of the pixels in the image in terms of count level will be shown with maximum brightness, and similarly for the lower one. These values apply independently to each colour channel if more than one is in use. Immediately below the sliders, the pixel values which correspond to minimum (black) and maximum brightness are displayed for each channel. If the image is not fairly completely covered, this control doesn't give you as much freedom as you might like - the user interface may be improved in future releases.

The following buttons are available on the toolbar:

### Export as EPS

Pops up a dialogue which will write the current plot as an EPS file.

### Export as GIF

Pops up a dialogue which will output the current plot to a GIF file. The output file is just the same as the plotted image that you see. Resize the plotting window before the export to control the size of the output GIF.

### FITS Export as FITS

Pops up a dialogue which will output the plotted map as a FITS array. If only one channel is visible (either one colour channel or monochrome mode) then the output FITS file will be a 2d array with dimensions the same as the displayed image. If there are multiple RGB channels then the output array will be 3d with the third dimension having an extent of 2 or 3, depending on the number of colour channels visible. In either case the FITS file will have a single (primary) HDU. Basic coordinate system information, as well as DATAMIN and DATAMAX cards, will be written to the header. The output array will have some integer type; its length (BITPIX) will depend on the maximum value of any of the pixels.

### Rescale

Rescales the axes of the current plot so that it contains all the data points in the currently selected subsets. By default the plot will be scaled like this, but it may have changed because

of changes in the subset selection or from zooming in or out.

### **Configure Axes**

Pops up a dialogue to allow manual configuration of axis ranges and labels - see Appendix A.4.1.2.

### **Log Intensity**

Toggles between linear and logarithmic mapping for colour intensity as a function of number of counts.

### **Replot**

Redraws the current plot. It is usually not necessary to use this button, since if you change any of the plot characteristics with the controls in this window the plot will be redrawn automatically. However if you have changed the data, e.g. by editing cells in the Data Window, the plot is not automatically redrawn (since this is potentially an expensive operation and you may not require it). Clicking this button redraws the plot taking account of any changes to the table data.

### **Colour**

Toggles between one-channel (monochrome) and three-channel (RGB) images. When the display is monochrome, the brightness of every pixel depends on the number of counts that fall in its bounds summed from every plotted dataset, and the display runs from black (low cut) to white (high cut) via shades of grey. For RGB, each dataset is assigned one of the colours red, green or blue, and the brightness of each colour is individually determined by the number of counts from datasets assigned that colour.

### **Bigger Pixels**

Increments the size of screen pixel corresponding to one density map bin.

### **Smaller Pixels**

Decrements the size of screen pixel corresponding to one density map bin.

### **Draw Subset Region**

Allows you to draw a region on the screen defining a new Row Subset. When you have finished drawing it, click this button again to indicate you're done. See Appendix A.4.1.3 for more details.

### **Subset From Visible**

Defines a new **Row Subset** consisting of only the points which are currently visible on the plotting surface. See Appendix A.4.1.3 for more explanation.

How to set the colour channel corresponding to each dataset is explained in the following subsection.

#### **A.4.7.1 Density Style Editor**

When you are doing a three-channel (RGB) density plot, each dataset is assigned a colour channel to which it contributes. A representation of this is displayed in a button to the right of its name in the dataset selector panel at the bottom of the density map window. If you click this button the following dialogue will pop up which enables you to change the colour channel

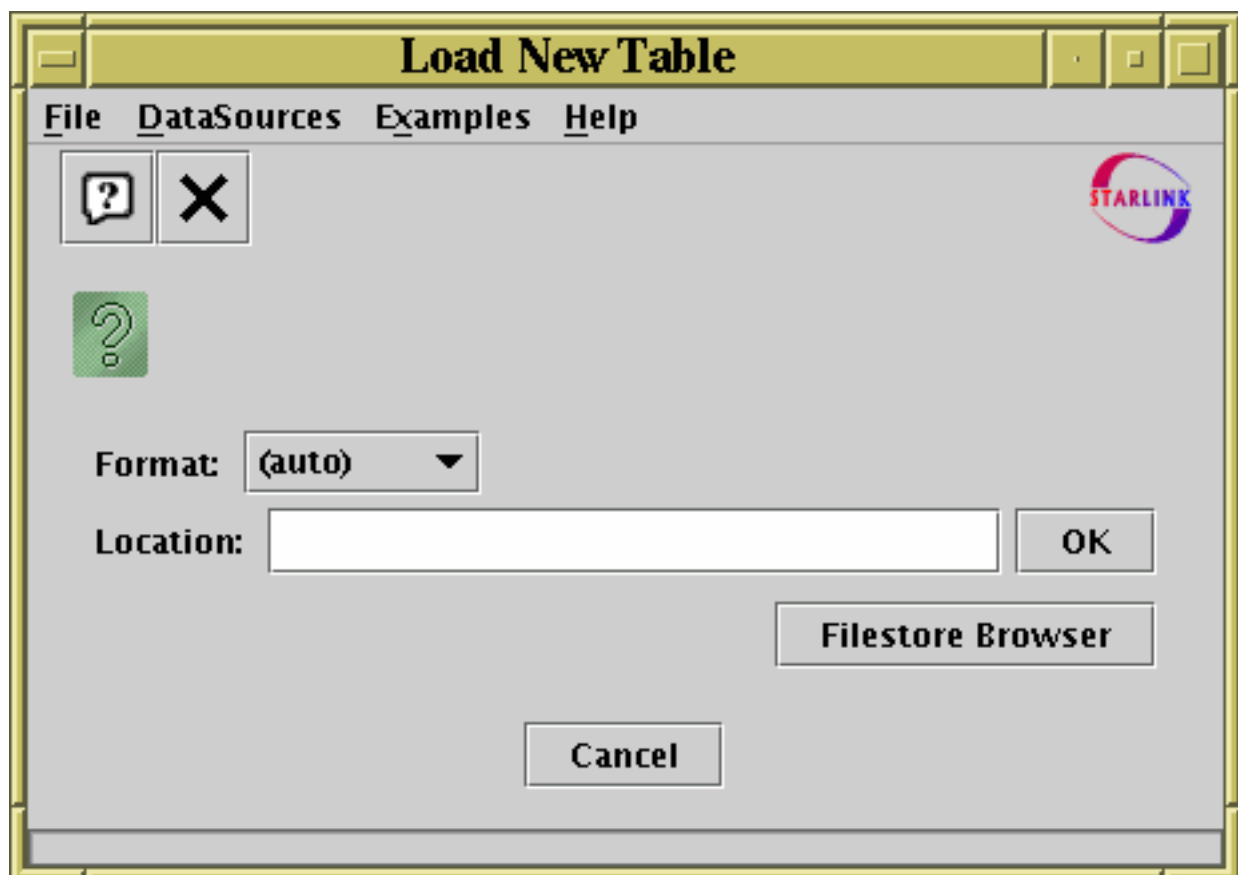

### Style editor dialogue for density map

The **Label** text box allows you to set the name which will be written in the plot's legend to label the dataset. By default this is derived from the Row Subset's name and, if it's not part of the main dataset, the name of the dataset's tab.

The **Channel** selector allows you to select either the Red, Green or Blue channel for this dataset to contribute to. Note that if plotting is in monochrome mode, this setting won't have any material effect on the appearance of the plot; also, the legend icons will appear monochrome in this case.

### A.5 Load Window

## Load Window

The Load Window is used for loading tables from an external location (e.g. disk or URL) into TOPCAT. It is obtained using the **Load Table** button () in the Control Window toolbar or File menu.

This dialogue allows you to specify a new table to open in several different ways, described below. If you successfully load a table using any of these options, a new entry will be added into the Table List in the Control Window, which you can then use in the usual ways. If you choose a location which can't be turned into a table (for instance because the file doesn't exist), a window will pop up telling you what went wrong. If you get an `OutOfMemoryError` while loading a table, you will have to run TOPCAT with more memory, as described in Section 9.2.2 or use the `-disk` flag described in Section 9.1.

In the simplest case, you can type a name into the **Location** field and hit return or the **OK** button. This location can be a filename or a URL, possibly followed by a '#' character and a 'fragment identifier' to indicate where in the file or URL the table is located; the details of what such fragment identifiers mean can be found in the relevant subsection within Section 4.1. You should select the relevant table format from the **Format** selector box - you can leave it on (**auto**) for loading FITS tables or VOTables, but for other formats such as ASCII or CSV you must select the right one explicitly (again, see Section 4.1 for details).

There are many other ways of loading tables however, described in the following subsections. The **Filestore Browser** button is always visible below the location field. Depending on startup options, there may be other buttons here. In any case, you can look in the **DataSources** menu to see other table load dialogues. Exactly which ones are available will depend on your setup (some may be absent or greyed out, and additional ones may be available). The following subsections describe some of the options which may be available.

### A.5.1 Filestore Browser

### Filestore Browser window

By clicking the **Filestore Browser** button in the Load Window, you can obtain a file browser which will display the files in a given directory. The way this window works is almost certainly familiar to you from other applications.

Unlike a standard file browser however, it can also browse files in remote filestores: currently supported are MySpace and SRB. MySpace is a distributed storage system developed for use with the Virtual Observatory by the AstroGrid project, and SRB (Storage Resource Broker) is a similar general purpose system developed at SDSC. To make use of these facilities, select the relevant entry from the selector box at the top of the window as illustrated above; this will show you a **Log In** button which prompts you for username, password etc, and you will then be able to browse the remote filestore as if it were local. The same button can be used to log out when you are finished, but the session will be logged out automatically when TOPCAT ends in any case. Access to remote filesystems is dependent on certain optional components of TOPCAT, and it may not be available if you have the topcat-lite configuration.

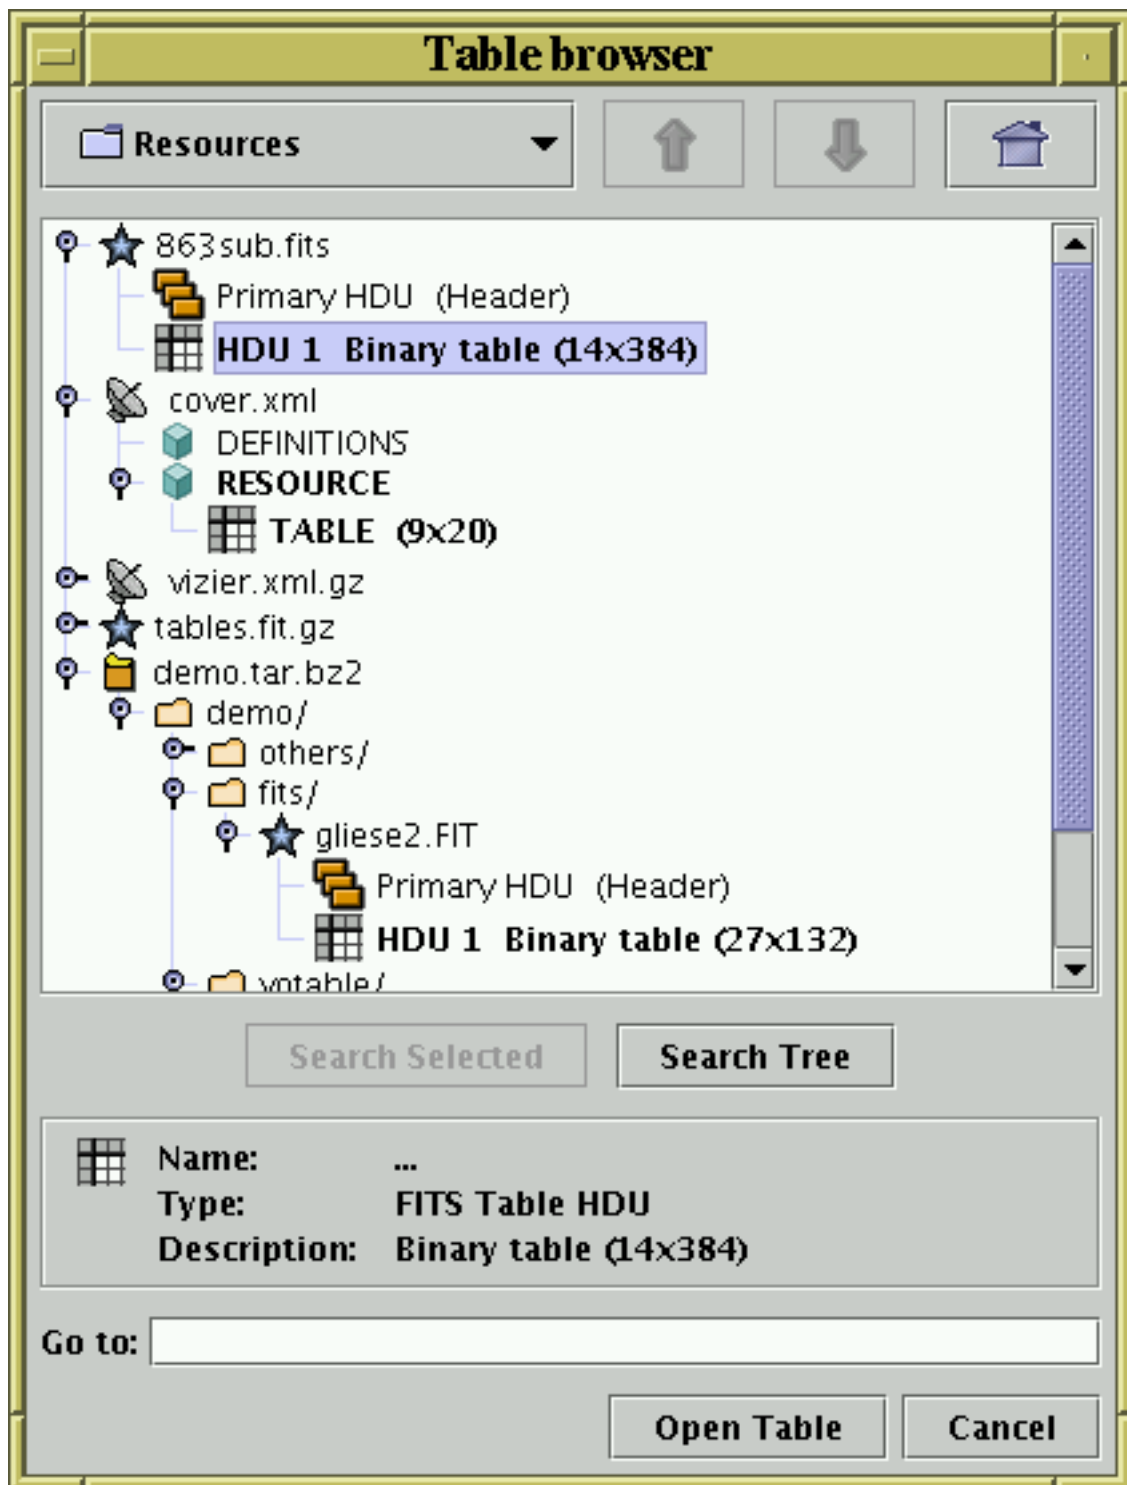

The browser initially displays the current directory, but this can be changed by typing a new directory into the **File Name** field, or moving up the directory hierarchy using the selector box at the top, or navigating the file system by clicking the up-directory button or double-clicking on displayed directories.

All files are shown, and there is no indication of which ones represent tables and which do not. To open one of the displayed files as a table, double-click on it or select it by clicking once and click the **Open Table** button. The **Table Format** selector must be set correctly: the "(auto)" setting will automatically detect the format of VOTable or FITS tables, otherwise you will need to select the

option describing the format of the file you are attempting to load (see Section 4.1). If you pick a file which cannot be converted into a table an error window will pop up.

In most cases, selecting the file name and possibly the format is all you need to do. However, the **Position in file** field allows you to add information about where in the file the table you want is situated. The meaning of this varies according to the file format: for FITS files, it is the index of the HDU containing the table you're after (the first extension after the primary HDU is numbered 1), and for VOTables it is the index of the TABLE element (the first TABLE encountered is numbered 0). If you leave this blank, you will get the first table in the file in question - many file formats only allow one table per file in any case. For a more table-aware view of the file system, use the Hierarchy Browser (Appendix A.5.2) instead.

### **A.5.2 Hierarchy Browser**

### File load Hierarchy Browser window

By selecting the **Hierarchy Browser** option from the Load Window's **DataSources** menu, you can obtain a browser which presents a table-aware hierarchical view of the file system. (Note that a freestanding version of this panel with additional functionality is available in the separate Treeview application).

This browser resembles the Filestore Browser in some ways, but with important differences:

- It shows the file system in a 'tree-like' fashion, so that multiple levels of the hierarchy are displayed at once
- It understands which items in the hierarchy represent tables that can be automatically detected and which represent other kinds of object (for instance directories, zip files, or plain text files)

- It can look inside hierarchical files, so for instance it can investigate a Tar or Zip archive which may contain table entries, or display multiple tabular HDUs in a FITS file, or multiple TABLE elements at different levels in a VOTable document

The main part of the window shows a "tree" representation of the hierarchy, initially rooted at the current directory. Each line displayed represents a "node" which may be a file or some other type of item (for instance an HDU in a FITS file or an entry in a tar archive). The line contains a little icon which indicates what kind of node it is and a short text string which gives its name and maybe some description. Nodes which represent tables are indicated by the  icon. For nodes which have

some internal structure there is also a "handle" which indicates whether they are collapsed () or expanded (). You can examine remote filespace (MySpace, SRB) as well as local ones in the same way as with the Filestore Browser.

If you select a node by clicking on it, it will be highlighted and some additional description will appear in the panel below the hierarchy display. The text is in **bold** if the node in question can be opened as a table, and non-bold if it is some non-table item.

**Note:** an important restriction of this browser is that it will only pick up tables which can be identified automatically - this includes FITS and VOTable files, but does not include text-based formats such as ASCII and Comma-Separated Values. If you want to load one of the latter types of table, you will need to use one of the other load methods and specify table format explicitly.

You can see how this browser works on an example directory of tables as described in Appendix A.5.5.

Note that this window requires certain optional components of the TOPCAT installation, and will not be available if you have the topcat-lite configuration.

### A.5.2.1 Navigation

Navigation is a bit different from navigation in the **File Browser** window. To expand a node and see its contents, click on its handle (clicking on the handle when it is expanded will collapse it again). When you have identified the table you want to open, highlight it by clicking on it, and then click the **Open Table** button at the bottom.

To move to a different directory, i.e. to change the root of the tree which is displayed, use one of the buttons above the tree display:

#### Selector box

Allows you to move straight to any directory higher up than the current one.

**Up**

Moves to the parent of the current directory.

**Down**

Moves to the currently selected (highlighted) node.

**Home**

Moves to the user's home directory.

Alternatively, you can type in a new directory in the **Go to** field at the bottom of the window.

(In fact the above navigation options are not restricted to changing the root to a new directory, they can move to any node in the tree, for instance a level in a Tar archive.)

### A.5.2.2 Table Searches

There are two more buttons in the browser, **Search Selected** and **Search Tree**. These do a recursive search for tables in all the nodes starting at the currently selected one or the current root respectively. What this means is that the program will investigate the whole hierarchy looking for any items which can be used as tables. If it finds any it will open up the tree so that they are visible (note that this doesn't mean that the only nodes revealed will be tables, ancestors and siblings will be revealed too). This can be useful if you believe there are a few tables buried somewhere in a deep directory structure or Tar archive, but you're not sure where. Note that this may be time-consuming - a busy cursor is displayed while the search is going on. Changing the root of the tree will interrupt the search.

### A.5.3 SQL Query

#### SQL Query Dialogue

If you want to read a table from an SQL database (Section 4.1.6), you can use a specialised dialogue to specify the SQL query by selecting **SQL Query** option from the Load Window's **DataSources** menu.

This provides you with a list of fields to fill in which make up the query, as follows:

#### Protocol

The name of the appropriate JDBC sub-protocol. This is defined by the JDBC driver that you are using, and is for instance "mysql" for MySQL's Connector/J driver or "postgresql" for PostgreSQL's JDBC driver.

#### Host

The hostname of the machine on which the database resides (may be "localhost" if the database is local).

#### Database name

The name of the database.

#### SQL Query

The text of the query which will define the resulting table. If you want to look at a table named XXX as it exists in the database, you can write something like "SELECT \* from XXX". In principle any SQL query on the database can be used here, but the details of what SQL syntax is permitted will be defined by the JDBC driver you are using.

#### User name

The username under which you wish to access the database. This is not strictly necessary if there is no access control for the database in question.

### Password

The password for the given username. Again, whether this is necessary depends on the access policy of the database.

There are a number of criteria which must be satisfied for SQL access to work within TOPCAT (installation of appropriate drivers and so on) - see Section 9.3. If you don't take these steps, this dialogue may be inaccessible.

## A.5.4 Cone Search

### Cone search table import dialogue

By selecting the **Cone Search** option from the Load Window's **DataSources** menu, you can obtain a dialogue which allows you to query one of a number of external web services for a catalogue of objects known in a given region of the sky.

When first displayed, this dialogue window will ask an external services registry for all the cone

search services on the net which have advertised their existence. When it has got the result, you will see a list of their names and titles in a table. For more information about each one, use the **Columns** menu to select what information, such as publisher, reference URL etc is displayed in the table. You can scroll up and down this table and select the one which you want to query by clicking on it.

Having selected one of the cone search services from the table, you need to specify the sky region in which you are interested. If you enter the name of an astronomical object into the **Object Name** field and hit the **Resolve** button, the coordinates will be entered into the **RA** and **Dec** fields below. Alternatively you can type the coordinates in directly, choosing either degrees or sexagesimal coordinates using the unit selector boxes. Enter the search radius too.

Having done this, hit the **OK** button. This will send the query to the service you selected and, if successful, load into TOPCAT a table containing all the objects in the region of the sky you have specified. The exact format of the returned table will depend on the service you have selected, but it will contain at least columns representing Right Ascension and Declination.

Note that this window requires certain optional components of the TOPCAT installation, and will not be available if you have the topcat-lite configuration.

### A.5.5 Example Tables

Provided with TOPCAT are some example tables, which you can access in a number of ways. The simplest thing is to start up TOPCAT with the "-demo" flag on the command line, which will cause the program to start up with a few demonstration tables already loaded in.

You can also load examples in from the **Examples** menu in the Load Window however. This contains the following options:

#### **Load Example Table**

Lloads in a single example table.

#### **Browse Demo Data**

Pops up a Hierarchy Browser (Appendix A.5.2) looking at a hierarchy of tables in different formats. This option is designed to show some of the organisational complexity which TOPCAT can handle when browsing tables.

Note these examples are a bit of a mixed bag, and are not all that exemplary in nature. They are just present to allow you to play around with some of TOPCAT's features if you don't have any real data to hand.

### A.6 Save Window

### Save Window

The Save Window is used to write tables out, and it is accessed using the **Save Table** button () in the Control Window's toolbar or File menu. Any table in the Control Window's table list can be written at any time; what is written is the Apparent Table corresponding to the currently selected table, which takes into account any modifications you have made to its data or appearance this session. The current **Row Subset** and **Row Order** are displayed in this window as a reminder of what you're about to save; if you modify the values in these selectors you will be modifying the Apparent Table in the usual way.

Any Row Subsets which have been defined on the table in the current session will not be saved themselves, but you can save information about subset membership by creating new boolean columns based on subsets using the "To Column" button () from the Subsets Window.

You can use the **Table Output Format** selector box to pick the format in which the table will be written from one of the supported output formats (Section 4.2). There is no default format, and it won't automatically save to the same format it was loaded from, but if you leave it on "(auto)" it will try to guess the format based on the filename given; for instance if you specify the name "out.fits", a FITS binary table will be written.

You can specify the location of the output table in these ways, which are described in the following

sections:

- Type in the location directly in the Output Location field (Appendix A.6.1)
- Use the **Filestore Browser** button to get a browser (Appendix A.6.2) that shows you local and remote files
- Use the **SQL table** button to get the SQL Output Dialogue (Appendix A.6.3)

In some cases, saving the table to the same name as it was loaded from can cause problems (e.g. an application crash which loses the data unrecoverably). In other cases, it's perfectly OK. The main case in which it's problematic is when editing an uncompressed FITS binary table on disk. TOPCAT will attempt to warn you if it thinks you are doing something which could lead to trouble; ignore this at your own risk.

There is no option to compress files on output (though you can of course compress them yourself once they have been written).

If the table is large, a progress bar indicating how near the save is to completion will appear. It is not advisable to edit the table during a save operation.

In some cases, when saving a table to a format other than the one from which it was loaded, or if some new kinds of metadata have been added, it may not be possible to express all the data and metadata from the table in the new format. For instance a WDC table can contain data which represent epoch (date), and this cannot be stored in a FITS table. In this case the table may be written with such columns missing. Some message to this effect may be output in this case.

### **A.6.1 Enter Location**

You can specify where to save a table by typing its location directly into the **Output Location** field of the Save Table window. This will usually be the name of a new file to write to, but could in principle be a URL or a SQL specifier.

### **A.6.2 Filestore Browser**

### Filestore Browser for table saving

By clicking the **Browse Filestore** button in the **Save Table** window, you can obtain a browser which will display the files in a given directory.

The browser initially displays the current directory, but this can be changed by typing a new directory into the **File Name** field, or moving up the directory hierarchy using the selector box at the top, or navigating the file system by clicking the up-directory button or double-clicking on displayed directories.

The browser can display files in remote filestores such as on MySpace or SRB servers; see the section on the load filestore browser (Appendix A.5.1) for details.

To save to an existing file, select the file name and click the **OK** button at the bottom; this will overwrite that file. To save to a new file, type it into the **File Name** field; this will save the table under that name into the directory which is displayed. You can (re)set the format in which the file will be written using the **Output Format** selector box on the right (see Section 4.2 for discussion of output formats).

### A.6.3 SQL Output Dialogue

### SQL table writing dialogue

If you want to write a table to an SQL database (Section 4.2.6), you can use a specialised dialogue to specify the table destination by clicking the **SQL Table** button in the **Save Table** window.

This provides you with a list of fields to fill in which define the new table to write, as follows:

#### Protocol

The name of the appropriate JDBC sub-protocol. This is defined by the JDBC driver that you are using, and is for instance "mysql" for MySQL's Connector/J driver or "postgresql" for PostgreSQL's JDBC driver.

#### Host

The hostname of the machine on which the database resides (may be "localhost" if the database is local).

#### Database name

The name of the database.

#### New table name

The name of a new table to write into the given database. Subject to user privileges, this will overwrite any existing table in the database which has the same name, so should be used with care.

#### User name

The username under which you wish to access the database. This is not strictly necessary if there is no access control for the database in question.

#### Password

The password for the given username. Again, whether this is necessary depends on the access policy of the database.

There are a number of criteria which must be satisfied for SQL access to work within TOPCAT (installation of appropriate drivers and so on) - see the section on JDBC configuration (Section 9.3). If you don't take these steps, this dialogue may be inaccessible.

## A.7 Other Windows

### A.7.1 Concatenation Window

### Concatenation Window

The Concatenation Window allows you to join two tables together top-to-bottom. It can be obtained using the **Concatenate Tables** button (  ) in the Control Window toolbar or Joins menu.

When two windows are concatenated all the rows of the first ("base") table are followed by all the rows of the second ("appended") table. The result is a new table which has a number of rows equal to the sum of the two it has been made from. The columns in the resulting table are the same as those of the base table. To perform the concatenation, you have to specify which columns from the appended table correspond to which ones in the base table. Of course, this sort of operation only makes sense if at least some of the columns in both tables have the same meaning. This process is discussed in more detail in Section 5.1.

The concatenation window allows you to select the base and appended tables, and for each column in the base table to specify which column in the appended table corresponds to it. You may select a blank for this, in which case the column in question will have all null entries in the resulting table. In some cases these column selectors may have a value filled in automatically if the program thinks it can guess appropriate ones, but you should ensure that it has guessed correctly in this case. Only suitable columns are available for choosing from these column selectors; in most cases this means numeric ones.

When you have filled in the fields to your satisfaction, hit the **Concatenate** button at the bottom of the window, and a new table will be created and added to the table list in the Control Window (a popup window will inform you this has happened).

The result is created from the Apparent (Section 3) versions of the base and appended tables, so that

any row subsets, hidden columns, or sorts currently in force will be reflected in the output.

### A.7.2 Pair Match Window

Pair Match Window

The Pair Match Window allows you to join two tables together side-by-side, aligning rows by matching values in some of their columns between the tables. It can be obtained using the **Pair Match** () button in the Control Window toolbar or **Joins** menu.

In a typical scenario you might have two tables each representing a catalogue of astronomical objects, and you want a third table with one row for each object which has an entry in both of the original tables. An object is defined as being the same one in both tables if the co-ordinates in both rows are "similar", for instance if the difference between the positions indicated by RA and Dec columns differ by no more than a specified angle on the sky. Matching rows to produce the join requires you to specify the criteria for rows in both tables to refer to the same object and what to do when one is found - the options are discussed in more detail in Section 5.2.

The result is created from the Apparent versions of the tables being joined, so that any row subsets, hidden columns, or sorts currently in force will be reflected in the output. Progress information on the match, which may take a little while, is provided in the logging window and by a progress bar at the bottom of the window. When it is completed, you will be informed by a popup window which indicates that a new table has been created. This table will be added to the list in the Control Window and can be examined, manipulated and saved like any other. In some cases, some additional columns will be added to the output table which give you more information about how it has progressed (see Appendix A.7.2.3).

The Match Window provides a set of controls which allow you to choose how the match is done and what the results will look like. It consists of these main parts:

**Match Criteria box**

Allows you to define what counts as a match between two rows.

**Column Selection boxes**

Allows you to select which tables are to be joined and which columns in them supply the matching coordinates.

**Output Rows selector**

Allows selection of which rows are to be included in the output table (for instance whether only those rows matching in both tables should be output or not).

**Log window**

Reports on progress as the match is taking place. The progress bar at the bottom of the window also provides an indication of how far through each stage processing has got.

**Control buttons**

The **Go** button starts the search when you are happy with the selections that you have made, and the **Stop** button interrupts it midway if you decide you no longer want the results (closing the Match Window also interrupts the calculation).

The following sections describe some of these components in more detail.

**A.7.2.1 Match Criteria**

The match criteria box allows you to specify what counts as a match between two rows. The selection you make in this box will determine which columns you have to fill in for the table(s) being matched in the rest of the window. In most cases what you are selecting here is the coordinate space in which rows will be compared against each other, and a numerical value or values to determine how close two rows have to be in terms of a metric on that space to count as a match.

The following match types are offered:

**Sky**

Comparison of positions on the celestial sphere. In this case you will need to specify columns giving Right Ascension and Declination for each table participating in the match. The Max Error value you must fill in is the maximum separation of matched points around a great circle.

**Sky with Errors**

The matching is like that for the **Sky** option above, but an error radius (positional uncertainty) can be given for each row in the input tables, rather than just a single value for the whole match. You need to specify a single Max Error value, which gives the global maximum separation applying to all matches, and for each of the input tables, along with the Right Ascension and Declination columns, you also specify an Error column which gives the error radius corresponding to that position. Two rows are considered to match when the separation between the two RA,Dec positions is smaller than *both* the Max Error value *and* the sum of the two Error values for the corresponding rows. If either of the per-row Error values is blank, then any separation up to the Max Error is considered to match. According to these rules, you might decide to set the Max Error to an arbitrarily large number so that only the sum of per-row Errors will determine the actual match criteria. However please *don't* do this, since the Max Error also functions as a tuning parameter for the matching algorithm, and ought to be reasonably close to the actual maximum acceptable separation - if necessary use the Statistics Window to determine the actual maximum uncertainty.

**Sky 3D**

Comparison of positions in the sky taking account of distance from the observer. In this case you will need to specify columns giving Right Ascension and Declination in angular units, as well as distance along the line of sight in arbitrary units for each table participating in the match. The Error value is a maximum separation in Cartesian space of matched points in the same units as the radial distance.

**Exact Value**

Requires exact matching of values. In this case you will need to specify the column containing the match key for each table participating in the match; this might typically be an object name or index number. Two rows count as matching if they have exactly the same entry in the specified field, except rows with a null value in that column, which don't match any other row.

**N-dimensional Cartesian**

Comparison of positions in an isotropic N-dimensional Cartesian space. In this case you will need to specify N columns giving coordinates for each table participating in the match. The Error value is the maximum spatial separation of matched points. Currently the highest dimensionality you can select is 3-d - does anyone want a higher number?

**N-dimensional Cartesian (anisotropic)**

Comparison of positions in an N-dimensional Cartesian space with an anisotropic metric. In this case you will need to specify N columns giving coordinates for each table participating in the match, and an error radius for each of these dimensions. Points P1 and P2 are considered to match if P2 falls within the ellipsoid defined by the error radii centered on P1. This kind of match will typically be used for non-'spatial' spaces, for instance (magnitude,redshift) space, in which the metrics in different dimensions are not related to each other. Currently the highest dimensionality you can select is 4-d - does anyone want a higher number?

**Sky + X**

Comparison of positions on the celestial sphere with an additional numeric constraint. This is a combination of the Sky and 1-d Cartesian matches above, so the columns you need to supply are RA, Dec and one extra, and the errors are angular separation on the sky and the error in the extra column. A match is registered if it matches in both of the constituent tests. You could use this for instance to match objects which are both close on the sky and have similar luminosities.

**Sky + XY**

Comparison of positions on the celestial sphere with an additional 2-d anisotropic Cartesian

constraint. This is a combination of the Sky and 2-d Anisotropic Cartesian matches above, so the columns you need to supply are RA, Dec and two extra, and the errors are angular separation on the sky and the error radii corresponding to the extra columns. A match is registered if it matches in both of the constituent tests. You could use this for instance to match objects which are both close on the sky and have similar luminosities and redshifts.

### HTM

Performs sky matching in just the same way as the **Sky** option above, but using a different algorithm (pixelisation of the celestial sphere is performed using the Hierarchical Triangular Mesh rather than the HEALPix scheme). The results in both cases should be identical, but HTM is much slower. Hence, this option is only useful for debugging. It may be withdrawn in future releases.

Depending on the match type, the units of the error value(s) you enter may be significant. In this case, there will be a unit selector displayed alongside the entry box. You must choose units which are correct for the number you enter.

### A.7.2.2 Column Selection Boxes

The column selection boxes allow you to select which of the columns in the input tables will provide the data (the coordinates which have to match). For each table you must select the names of the required columns; the ones you need to select will depend on the match criteria you have chosen.

For some columns, such as Right Ascension and Declination in sky matches, units are important for the columns you select. In this case, there will be a selector box for the units alongside the selector box for the column itself. You must ensure that the correct units have been selected, or the results of the match will be rubbish.

In some cases these column and/or unit selectors may have a value filled in automatically (if the program thinks it can guess appropriate ones) but you should ensure that it has guessed correctly in this case. Only suitable columns are available for choosing from these column selectors; in most cases this means numeric ones.

### A.7.2.3 Output Rows Selector Box

When the match is complete a new table will be created which contains rows determined by the matches which have taken place. The **Output Rows** selector box allows you to choose on what basis the rows will be included in the output table as a function of the matches that were found.

In all cases each row will refer to only one matched (or possibly unmatched) "object", so that any non-blank columns in a given row come from only rows in the input tables which match according to the specified criteria. However, you have two (somewhat interlinked) choices to make about which rows are produced.

The **Match Selection** selector allows you to choose what happens when a given row in one table can be matched by more than one row in the other table. There are two choices:

#### Best Match Only

Only the best match is chosen, and the other correct but inferior matches are ignored. The best match is usually the "closest" - it is the one with the lowest match score, where the definition of this score is determined by the match criteria you have selected.

#### All Matches

Any pairs which meet the match criteria are retained in the output table. This means that you may have data from some of the same input rows appearing more than once in the output.

The **Join Type** selector allows you to choose what output rows result from a match in the input tables.

### **1 and 2**

The output table contains only rows which have an entry from both of the input tables, so that every output row represents an actual matched pair.

### **All from 1**

All of the matched rows are present in the output as for **1 and 2**, but additionally the unmatched rows from the first table are present with the columns from the second table blank.

### **All from 2**

As for **All from 1** but the other way round.

### **1 or 2**

Every row, matched and unmatched, from both of the input tables appears in the output. This is the union of rows from **All from 1** and **All from 2**.

### **1 not 2**

This presents all the rows in the first table which do *not* have matches in the second table. Consequently, it only contains columns from the first table, since all the entries from the second one would be blank in any case.

### **2 not 1**

The same as **1 not 2** but the other way round.

### **1 xor 2**

The "exclusive or" of the match - the output only contains rows from the first table which don't have matches in the second table and vice versa. It is the union of **1 not 2** and **2 not 1**.

In most cases (all the above except for **1 not 2** and **2 not 1**, the set of columns in the output table contains all the columns from the first table followed by all the columns from the second table. If this causes a clash of column names, offending columns will be renamed with a trailing "\_1" or "\_2". Depending on the details of the match however, some additional useful columns may be added:

### **Match Score**

For rows that represent a match, a numeric value representing how good the match was will usually be present. This is typically a separation in real or notional space - for instance for a **Sky** match it is the distance between the two matched celestial positions in arcseconds along a great circle. It will always be greater than or equal to zero, and a smaller value represents a better match. The name and exact meaning of this column depends on the match criteria - examine its description in the Columns Window for details.

### **GroupSize, GroupID**

If you choose the **All Matches** option and some of the rows match more than once, two columns named **GroupID** and **GroupSize** will be added. These allow you to identify which matches are multiple. In the case of rows which represent a unique match, they are blank. But for rows which represent a set of multiple matches, the GroupSize value tells you how many rows participate in this match, and the GroupID value is an integer which is the same for all the rows which participate in the same match. So if you do a sort on the GroupID value, you'll see all the rows in the first non-unique match group together, followed by all the rows in the second non-unique group... and after them all the unique matches.

Here is an example. If your input tables are these:

X	Y	Vmag
-	-	----

```

1134.822    599.247    13.8
 659.68     1046.874   17.2
 909.613    543.293     9.3
    
```

and

```

  X           Y           Bmag
  -           -           ----
909.523     543.800     10.1
1832.114     409.567     12.3
1135.201     600.100     14.6
 702.622    1004.972     19.0
    
```

then a Cartesian match of the two sets of X and Y values with an error of 1.0 using the **1 and 2** option would give you a result like this:

```

  X_1      Y_1      Vmag    X_2      Y_2      Bmag    Separation
  ---      ---      ----    ---      ---      ----    -
1134.822  599.247   13.8   1135.201  600.100   14.6     0.933
 909.613  543.293    9.3     909.523  543.800   10.1     0.515
    
```

using **All from 1** would give you this:

```

  X_1      Y_1      Vmag    X_2      Y_2      Bmag    Separation
  ---      ---      ----    ---      ---      ----    -
1134.822  599.247   13.8   1135.201  600.100   14.6     0.933
 659.68    1046.874   17.2
 909.613  543.293    9.3     909.523  543.800   10.1     0.515
    
```

and **1 not 2** would give you this:

```

  X           Y           Vmag
  -           -           ----
 659.68     1046.874   17.2
    
```

### A.7.3 Internal Match Window

### Internal Match Window

The Internal Match Window allows you to perform matching between rows of the same table, grouping rows that have the same or similar values in specified columns and producing a new table as a result. It can be obtained by using the **Internal Match** (  ) button in the Control Window toolbar or **Joins** menu.

You might want to use this functionality to remove all rows which refer to the same object from an

object catalogue, or to ensure that only one entry exists for each object, or to identify groups of several "nearby" objects in some way.

The result is created from the Apparent versions of the tables being joined, so that any row subsets, hidden columns, or sorts currently in force will be reflected in the output. Progress information on the match, which may take some time, is provided in the logging window and by a progress bar at the bottom of the window. When it is completed, you will be informed by a popup window which indicates that a new table has been created. This table will be added to the list in the Control Window and can be examined, manipulated and saved like any other.

The window has the following parts:

**Match Criteria box**

Allows you to define what counts as a match between two rows (the same as for pair matching).

**Column Selection box**

Allows you to select which table to operate on and which columns supply the matching coordinates (the same as for pair matching).

**Match Action box**

Allows you to select what will be done (what new table will be created) when the matching groups of rows have been identified.

**Log Panel**

Displays progress as the match is taking place. The progress bar at the bottom of the window also provides an indication of how far through each stage processing has got.

**Control buttons**

The **Go** button starts the search when you are happy with the selections that you have made, and the **Stop** button interrupts it midway if you decide you no longer want the results (closing the Match Window also interrupts the calculation).

### A.7.3.1 Internal Match Action box

The Internal Match Action box gives a list of options for what will happen when an internal match calculation has completed. In each case a new table will be created as a result of the match. The options for what it will look like are these:

**Mark Groups of Rows**

The result is a table the same as the input table but with two additional columns: **GroupID** and **GroupSize**. Each group of rows which matched is assigned a unique integer, recorded in the GroupID column, and the size of each group is recorded in the GroupSize column. Rows which don't match any others (singles) have null values in both these columns. So for example by sorting the resulting table on GroupID you can group rows that match next to each other; or by sorting on GroupSize you can see all the pairs, followed by all the triples, ...

You can use this information in other ways, for instance if you create a new Row Subset using the expression `"GroupSize == 5"` you could select only those rows which form part of 5-object clusters.

**Eliminate All Grouped Rows**

The result is a new table containing only "single" rows, that is ones which don't match any other rows in the table according to the match criteria. Any rows which match are thrown out.

**Eliminate All But First of Each Group**

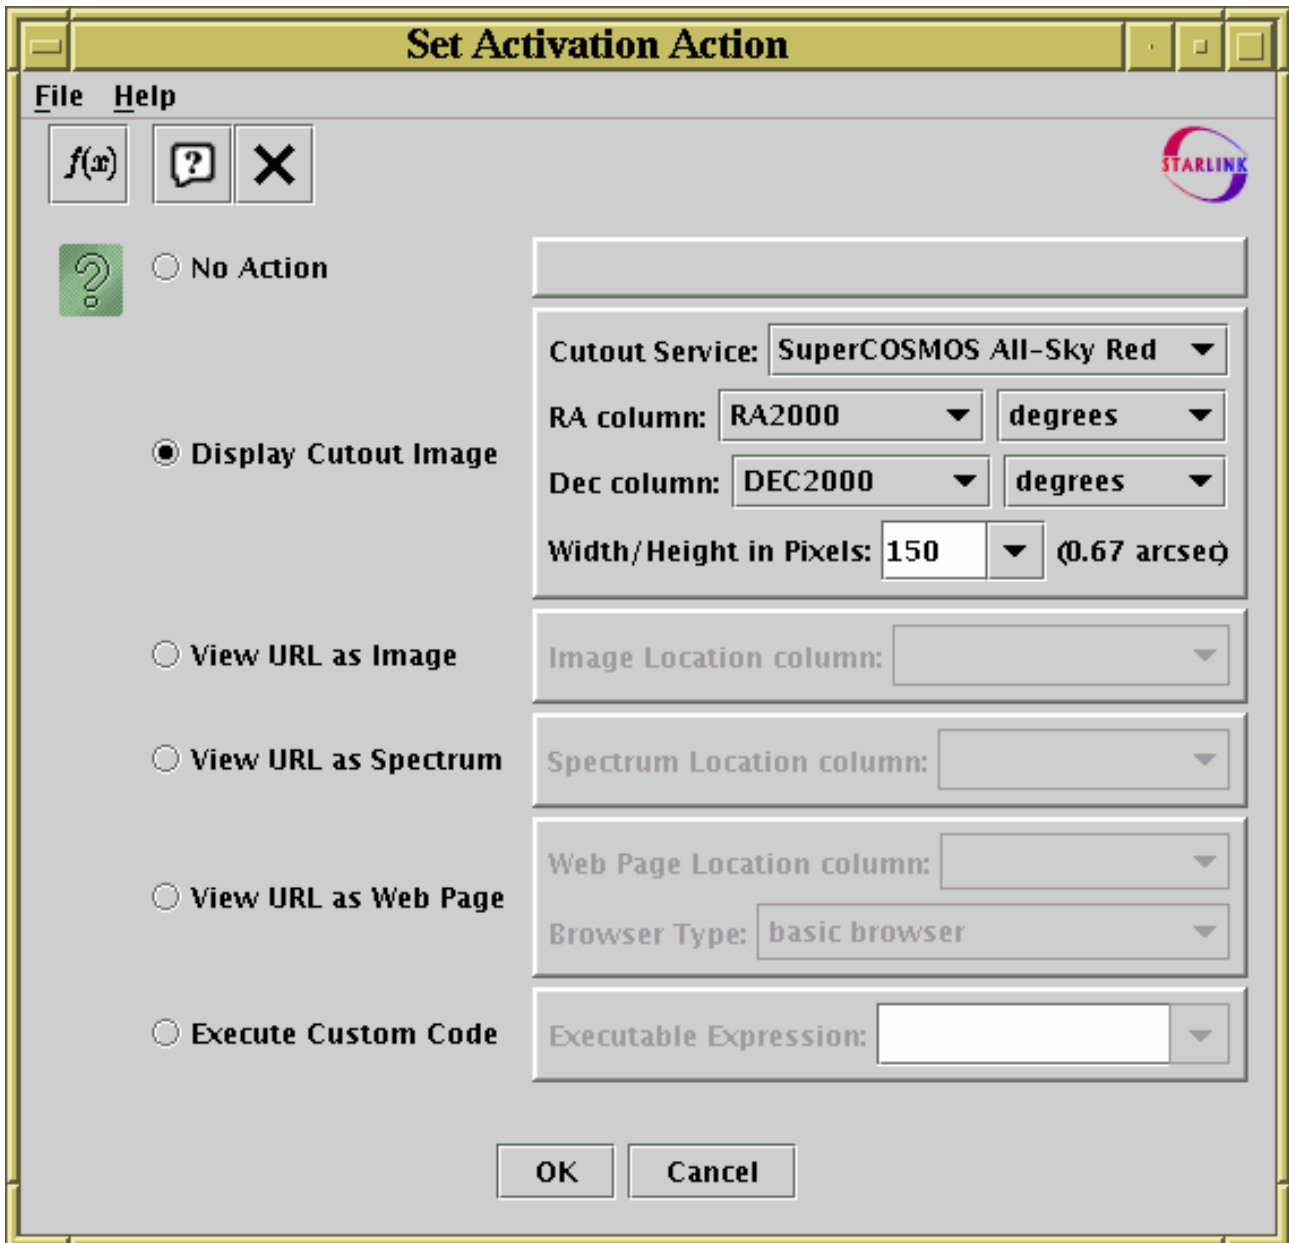

The result is a new table in which only one row (the first in the input table order) from each group of matching ones is retained. A subsequent internal match with the same criteria would therefore show no matches.

### New Table With Groups of Size N

The result is a new "wide" table consisting of matched rows in the input table stacked next to each other. Only groups of exactly N rows in the input table are used to form the output table; each row of the output table consists of the columns of the first group member, followed by the columns of the second group member and so on. The output table therefore has N times as many columns as the input table. The column names in the new table have "\_1", "\_2", ... appended to them to avoid duplication.

#### A.7.4 Activation Window

#### Activation Window

The Activation Window allows you to configure an action to perform when a table row is activated (Section 7) by clicking on a row in the Data Window or a point in the Plot Window. It can be obtained by clicking the **Activation Action** selector at the bottom of the properties panel in the Control Window.

You have various options for how to define the action. On the left of the window is a list of options; you have to choose one of these to determine what kind of action will take place. When you click

on one of these options the corresponding controls on the right hand side will become enabled: use these to select the details of the action and then click the **OK** button so that subsequent activation events will cause the action you have defined (or **Cancel** so that they won't). When you click OK the **Activation Action** in the control window will indicate the action you have configured.

The available options are as follows:

#### **No Action**

If this is selected, no special action will take place when a row is activated. This is the default.

#### **Display Cutout Image**

This option presents an easy-to-use way of popping up a cutout image from an image server displaying a region of sky around an activated row. You need to select the columns in your table which represent Right Ascension and Declination, including the units in which they are entered in the table (TOPCAT may be able to guess some or all of this information based on column names, UCDS and unit values, in which case it will enter its guesses in the selectors for you to accept or change). You also need to select the size in pixels of the image you want to see and the name of the survey which will supply the image from one of the listed ones:

- SuperCOSMOS All-Sky Blue
- SuperCOSMOS All-Sky Red
- SDSS Colour Images (note does not provide all-sky coverage)

When you activate the row, the program will attempt to contact the web server which provides these images, retrieve the image, and display it in an image viewer window.

#### **View URL as Image**

This option is suitable if one of the columns in your table gives the location (filename or URL) of an image file. The image may be in FITS, GIF, JPEG or PNG format, optionally compressed using gzip, Unix compress, or bzip2 format. Select the column which contains the location, and activating a row will pop up an image viewer to display it. See Appendix A.7.4.1 for more information about image viewers.

#### **View URL as Spectrum**

This option is suitable if one of the columns in your table gives the location (filename or URL) of a spectrum file. The spectrum may be in FITS or text format, optionally compressed. Select the column which contains the location, and activating a row will try to pop up a spectrum viewer to display it. Note this may not be possible if some components are not installed - see Appendix A.7.4.2 for information about spectrum viewers.

#### **View URL as Web Page**

This option is suitable if one of the columns in your table gives the location (filename or URL) of a web page; this should normally be in HTML or plain text, but depending on what browser you use other kinds of document may be supported. Select the column which contains the location and the browser which you would like to use for display, and activating a row will try to pop up a browser window to display it. See Appendix A.7.4.3 for more information about browsers.

#### **Execute Custom Code**

This option must be used if none of the others (which are fairly restrictive) do what you want. It is highly flexible, but not so easy to use. What you have to do is to write an expression following the rules in Section 6 involving some of the column names which will be invoked when a row is activated. This expression will typically have the effect of popping up an image or a spectrum in a viewer, but, especially if you link in your own functions (see Section 6.8) it can do pretty much anything.

Functions which are expected to be useful for activation actions are described in Appendix B.2 and include some general-purpose ones (`displayImage` and `displaySpectrum` to display an image or spectrum in an external viewer) as well as a few which are relevant to particular survey data, for instance the `spectra2QZ()` function, which will pop up a spectrum viewer

displaying all the spectra related to a given row of 2QZ survey data based on the contents of its NAME column.

As the above list shows, most of the activation actions you can define result in a viewer window of some kind popping up. Exactly what kind of viewer is used depends on how TOPCAT is set up and in some cases on your choices. More details of the viewer programs available are given in the following subsections. If these don't do what you want, you can use the **Execute Custom Code** option, perhaps in conjunction with user-defined functions or the `System.exec()` functions described in Appendix B.2, to invoke your own.

#### A.7.4.1 Image Viewer Applications

If you choose the **Display Cutout Image** or **View URL as Image** option in the Activation Window, then activating a row will display an image in an image viewer.

The default image viewer is SoG (<http://www.starlink.ac.uk/sog/>), an astronomical image viewer based on JSky, which offers colourmap manipulation, image zooming, graphics overlays, and other features. For this to work JAI, otherwise known as Java Advanced Imaging (<http://java.sun.com/products/java-media/jai/>) must be installed. JAI is a free component available from Sun, but not a part of the Java 2 Standard Edition by default. In operation, SoG looks like this:

### SoG Image Viewer

If JAI or the SoG classes themselves are absent, a fallback viewer which just displays the given image in a basic graphics window with no manipulation facilities is used. The fallback image viewer looks like this:

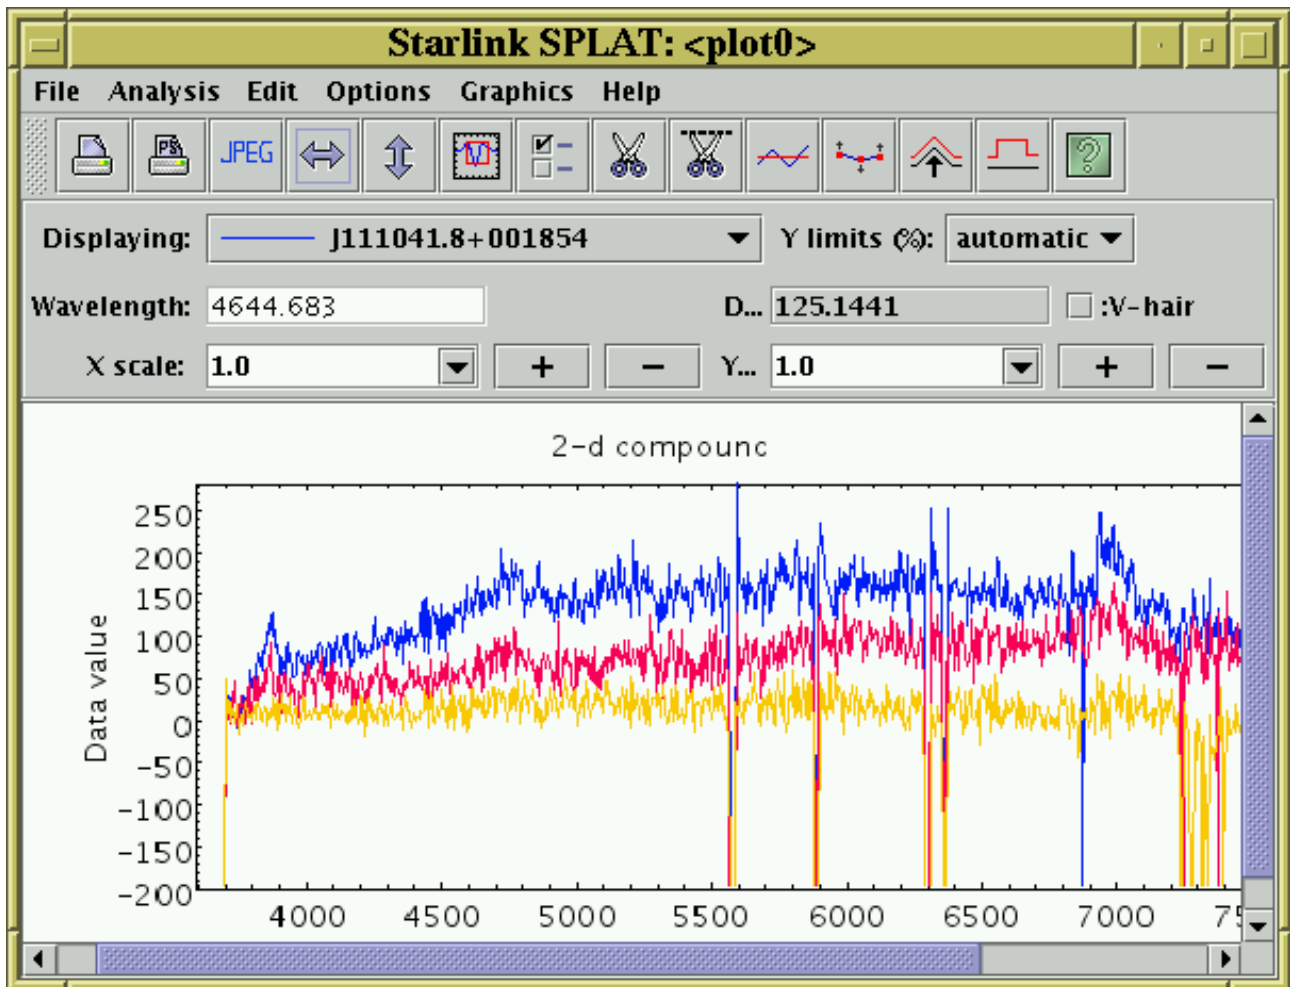

### Fallback Image Viewer

#### A.7.4.2 Spectrum Viewers

If you choose the **View URL as Spectrum** option in the Activation Window, then activating a row will display a spectrum in a spectrum viewer.

The default spectrum viewer is SPLAT (<http://www.starlink.ac.uk/splat/>), a sophisticated multi-spectrum analysis program. This requires the presence of a component named JNIAST, which may or may not have been installed with TOPCAT (it depends on some non-Java, i.e. platform-specific code). There is currently no fallback spectrum viewer, so if JNIAST is not present, then spectra cannot be displayed. In this case it will not be possible to select the **Display Named Spectrum** item in the Activation Window. An example of SPLAT display of multiple spectra is shown below.

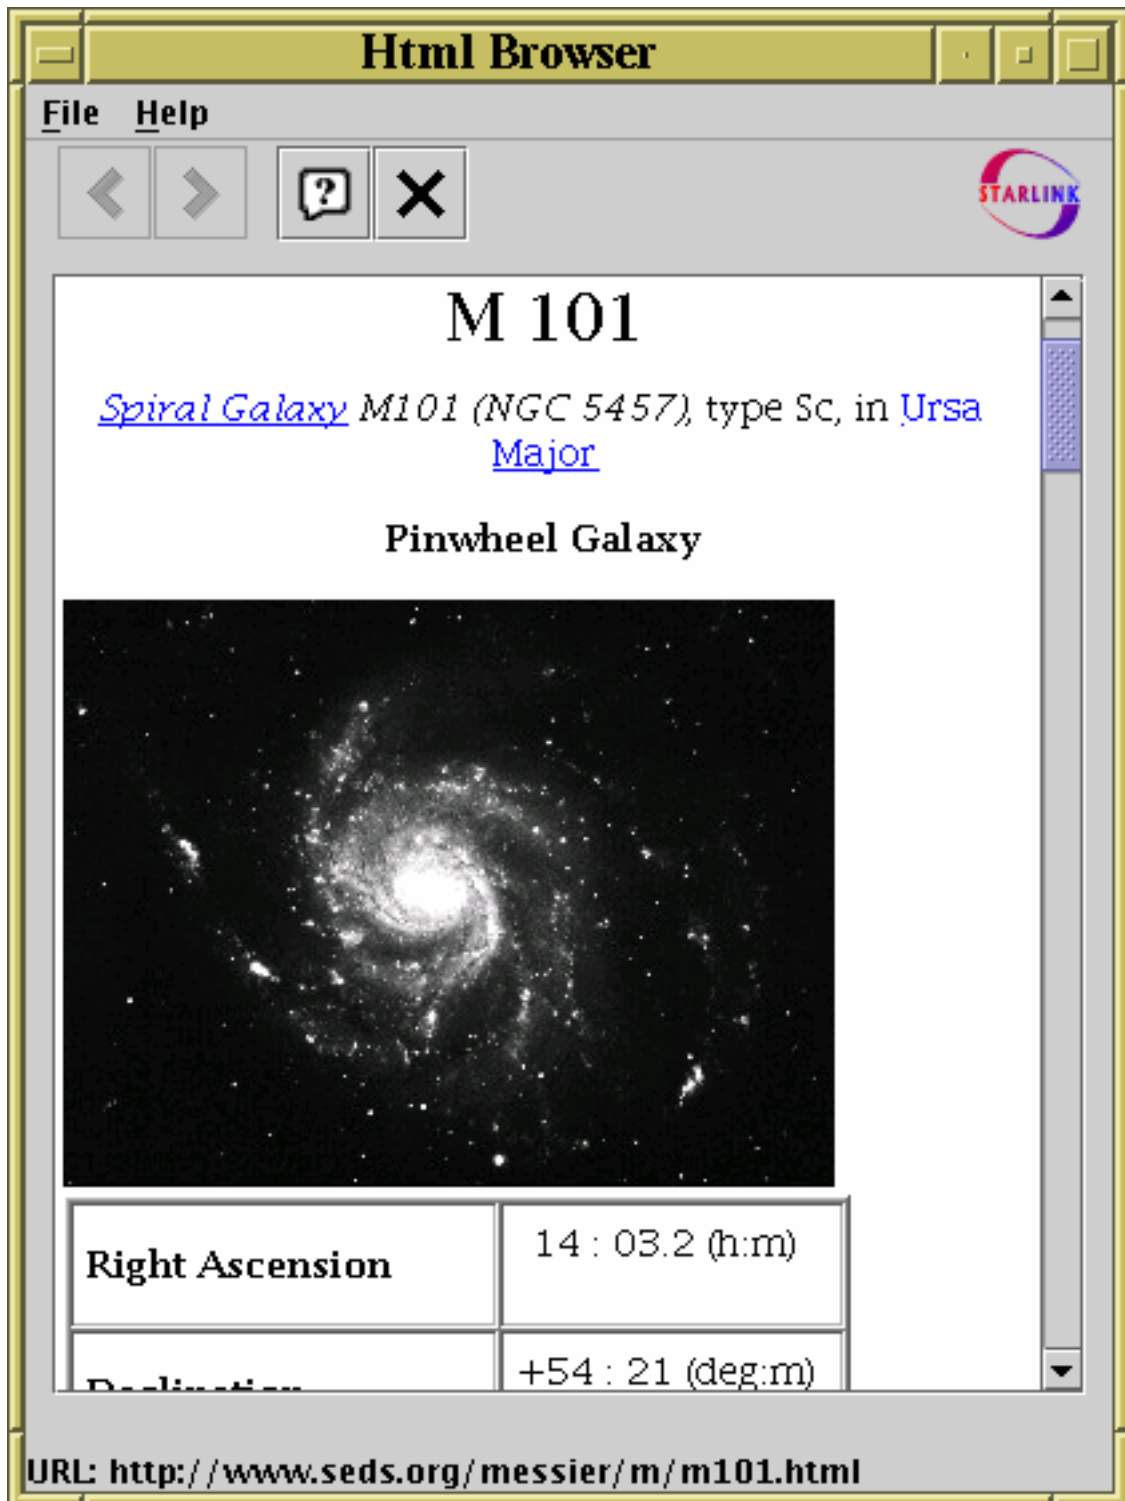

### SPLAT Spectrum Viewer

Full documentation for SPLAT is available on-line within the program, or in SUN/243.

#### A.7.4.3 Web Browsers

If you choose the **View URL as Web Page** option in the **Activation Window**, then activating a row will display the web page whose URL is in one of the columns in a web browser. You are given the option of what browser you would like to use in this case.

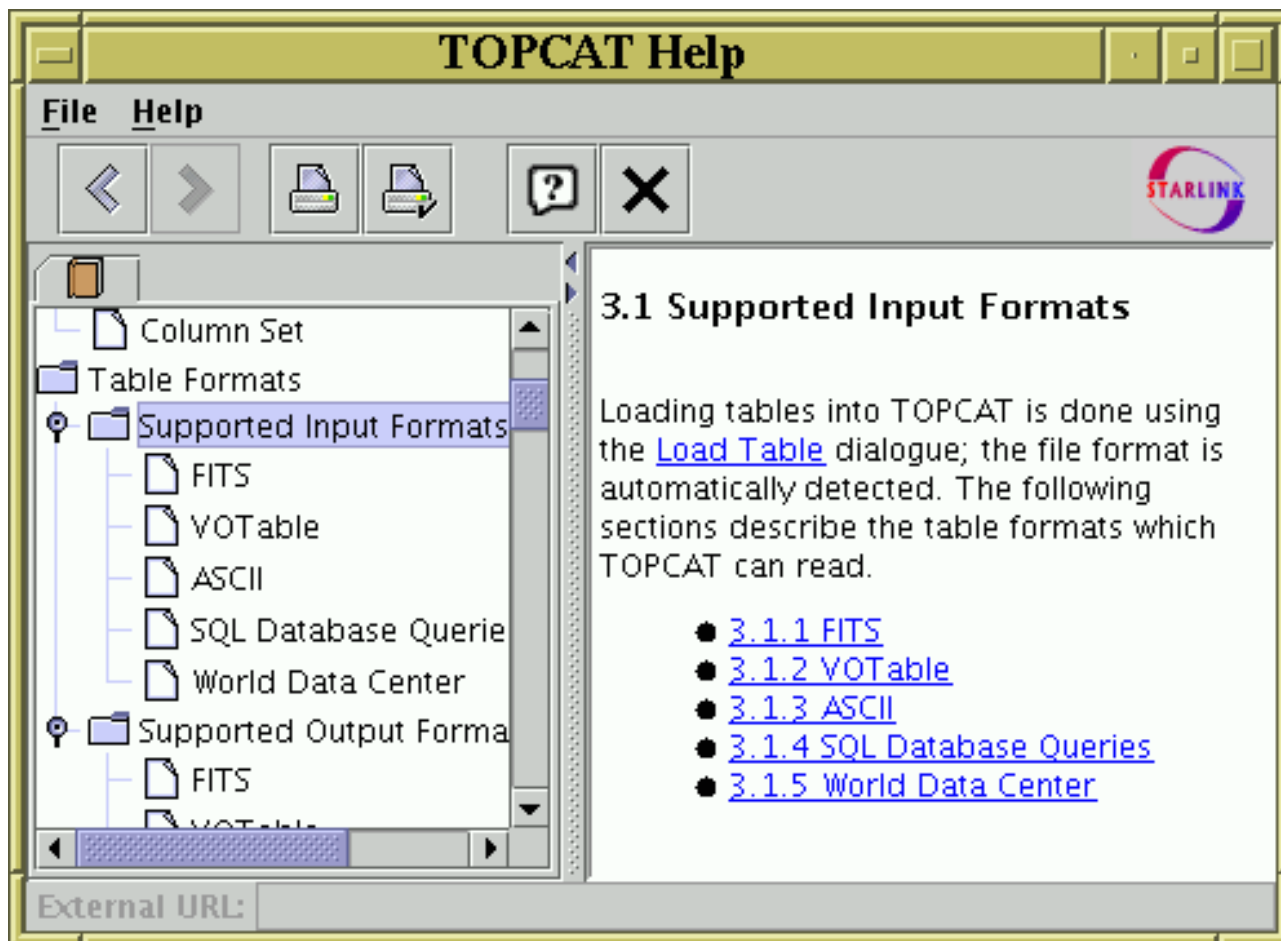

The default **basic browser** option uses a simple browser which can view HTML or plain text pages and has forward and back buttons which work as you'd expect. In many cases this is fine for viewing HTML pages, and it is available regardless of the system that you are running TOPCAT on. It looks like this:

### Basic HTML browser

In some circumstances, it's possible to use your normal web browser for web page display instead. The list of browsers currently includes Firefox, Mozilla and Netscape as well as the basic one. Selecting these will generally only work if (1) the browser you select is installed and on your path, (2) you're on some Unix-like operating system, (3) the browser is already running when the action is invoked. In this case, the selected URL should be displayed in an existing browser window rather than opening a new one. Doing it this way has the advantage that your browser can probably display many types of document (perhaps using plugins) as well as HTML.

### A.7.5 Help Window

## Help Window

The help window is a browser for displaying help information on TOPCAT; it can be obtained by clicking the **Help** () button that appears in the toolbar of most windows. It views the text

contained in this document, so it may be what you are looking at now. The panel on the left hand side gives a hierarchical view of the available help topics, and the panel on the right hand side displays the help text itself. The bar in between the two can be dragged with the mouse to affect the relative sizes of these windows.

The toolbar contains these extra buttons:

**Back**

Moves backward through the list of topics in the order you have looked at them.

**Forward**

Moves forward through the list of topics in the order you have looked at them.

**Print**

Pops up a dialogue to permit printing of the current page to a file or printer (but see below).

**Page Setup**

Pops up a dialogue to do printer setup.

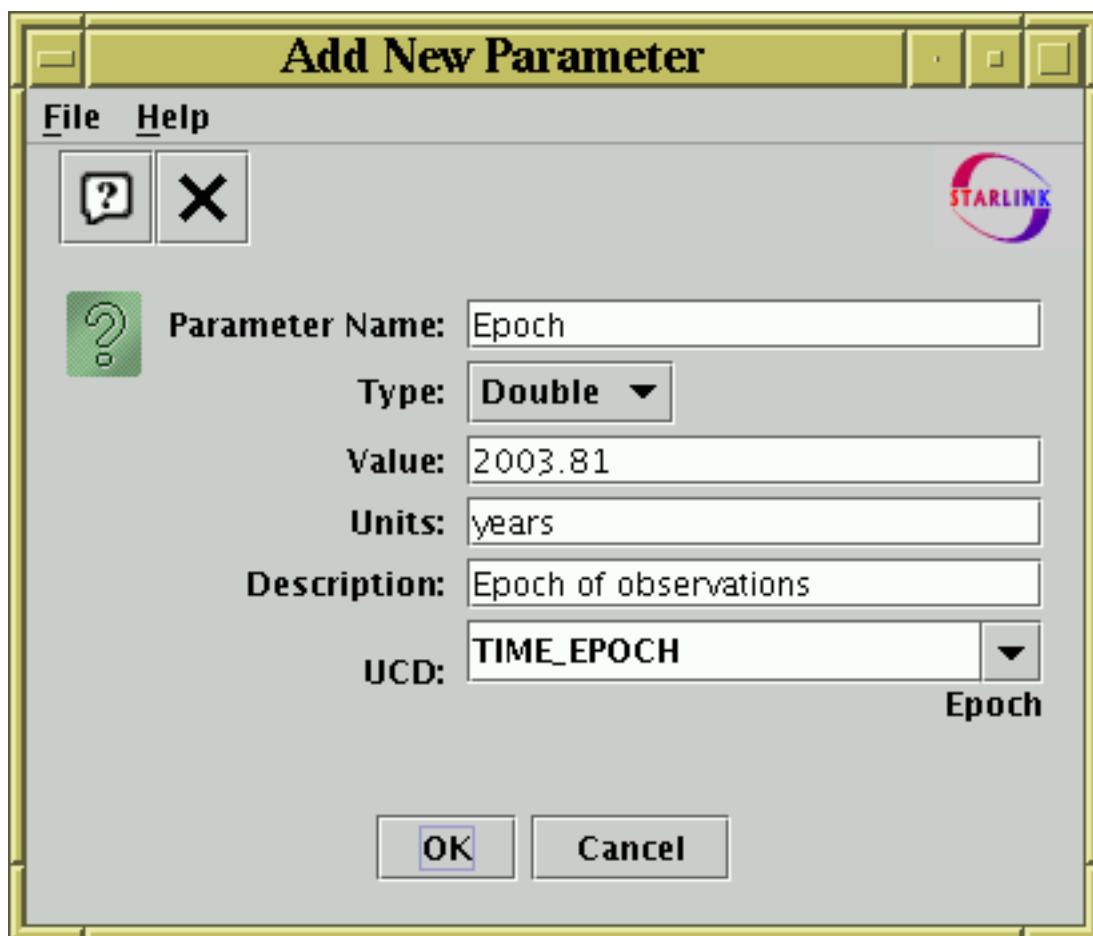

Although the printing buttons work, if you want to print out the whole of this document rather than

just a few sections you may be better off printing the PDF version, or printing the single-page HTML version through a web browser. The most recent version of these should be available on the web at <http://www.starlink.ac.uk/topcat/sun253/sun253.html> and <http://www.starlink.ac.uk/topcat/sun253.pdf>; you can also find the HTML version in the topcat jar file at [uk/ac/starlink/topcat/help/sun253.html](http://www.starlink.ac.uk/topcat/help/sun253.html) or, if you have a full TOPCAT installation, in [docs/topcat/sun253/sun253.html](http://www.starlink.ac.uk/topcat/docs/topcat/sun253/sun253.html) and [docs/topcat/sun253.pdf](http://www.starlink.ac.uk/topcat/docs/topcat/sun253.pdf) (the single-page HTML version is available here in the HTML version).

The help browser is an HTML browser and some of the hyperlinks in the help document point to locations outside of the help document itself. Selecting these links will go to the external documents. When the viewer is displaying an external document, its URL will be displayed in a line at the bottom of the window. You can cut and paste from this using your platform's usual mechanisms for this.

### A.7.6 New Parameter Window

#### New Parameter dialogue window

The New Parameter window allows you to enter a new table parameter to be added to a table. It can be obtained by clicking the **New Parameter** (+) button in the Appendix A.3.2. A parameter is simply a fixed value attached to a table and can contain information which is a string, a scalar, an array... in fact exactly the same sorts of values which can appear in table cells.

The window is pretty straightforward to use: fill in the fields and click **OK** to complete the addition. The **Type** selector allows you to select what kind of value you have input. The only compulsory field is **Parameter Name**; any of the others may be left blank, though you will usually want to fill in at least the **Value** field as well. Often, the parameter will have a string value, in which case the

**Units** field is not very relevant.

### A.7.7 Synthetic Column Window

#### Synthetic Column dialogue window

The Synthetic Column Window allows you to define a new "Synthetic" column, that is one whose values are defined using an algebraic expression based on the values of other columns in the same row. The idea is that the value of the cells in a given row in this column will be calculated on demand as a function of the values of cells of other columns in that row. You can think of this as providing functionality like that of a column-oriented spreadsheet. You can activate the dialogue using the **Add Column** (+) or **Replace Column** (↪) buttons in the Columns Window or

from the (right-click) popup menu in the Data Window.

The window consists of a number of fields you must fill in to define the new column:

#### Name

The name of the new column. This should preferably be unique (different from all the other column names). It will be easier to use it in algebraic expressions if it is also:

- Different from other columns even apart from upper/lower case distinctions
- In the form of a java identifier (starts with a letter, continues with alphanumerics including underscore)
- Not too long

#### Expression

This is the algebraic expression which defines the values that the cells in the new column of the table will have. The rules for writing algebraic expressions are described in Section 6, and detailed documentation of the functions you can use can be seen in the Available Functions

Window, which you can see by clicking the **Show Functions** ( $f(x)$ ) button on the toolbar.

### Units

The units of the column. If the quantity it represents is dimensionless or you don't know the units, this can be left blank. It would be a good idea to use a similar format for the units to that used for the existing columns in the table.

### Description

A short textual description of what the values contained by this column are. May be left blank.

### UCD

A Unified Content Descriptor for the column; a UCD is a semantic label attached to the column indicating what kind of quantity it contains by picking one option from a list defined by the CDS. The list of known UCDs is available via a selection box, or you can type a UCD in by hand. You may leave this blank if the you do not wish to assign a UCD to the column. A brief description of the UCD selected is visible below selection box itself.

### Index

Determines the position in the displayed table at which the new column will initially appear.

Of these, the **Expression** is the only one which must be filled in.

Having filled in the form to your satisfaction, hit the **OK** button at the bottom and the new column will be added to the table. If you have made some mistake in filling in the fields, a popup window will give you a message describing the problem. This message may be a bit arcane - try not to panic and see if you can rephrase the expression in a way that the parser might be happier with. If you can't work out the problem, it's time to consult your friendly local Java programmer (failing that, your friendly local C programmer may be able to help) or, by all means, contact the author.

If you wish to add more metadata items you can edit the appropriate cells in the Columns Window. You can edit the expression of an existing synthetic column in the same way.

Once created, a synthetic column is added to the Apparent Table and behaves just like any other; it can be moved, hidden/revealed, used in expressions for other synthetic columns and so on. If the table is saved the new column and its contents will be written to the new output table.

## A.7.8 Sky Coordinates Window

The screenshot shows a dialog box titled "Sky Coordinate Columns". It features a menu bar with "File" and "Help", a help button (question mark), and a close button (X). A STARLINK logo is located in the top right corner. The dialog is divided into two main sections: "Input Coordinates" and "Output Coordinates".

**Input Coordinates:**

- System:
- Units:
- Right Ascension:
- Declination:

**Output Coordinates:**

- System:
- Units:
- Longitude:
- Latitude:

At the bottom of the dialog are "OK" and "Cancel" buttons.

## Sky Coordinates Window

The Sky Coordinates Window allows you to add new columns to a table, representing coordinates in a chosen sky coordinate system. The table must already contain columns which represent sky coordinates; by describing the systems of the existing and of the new coordinates, you provide enough information to calculate the values in the new columns. You can activate this dialogue using the **New Sky Coordinate Columns** () button in the Columns Window.

The dialogue window has two halves; on the left you give the existing columns which represent sky coordinates, their coordinate system (fk5, fk4, galactic, supergalactic or ecliptic) and the units (degrees, radians or sexagesimal) that they are in. Note that the columns available for selection will depend on the units you have selected; for degrees or radians only numeric columns will be selectable, while for sexagesimal (dms/hms) units only string columns will be selectable. On the right you make the coordinate system and units selections as before, but enter the names of the new columns in the text fields. Then just hit the **OK** button, and the new columns will be appended at the right of the table.

### A.7.9 Algebraic Subset Window

#### Algebraic Subset dialogue window

The Algebraic Subset Window allows you to define a new Row Subset which uses an algebraic expression to define which rows are included. The expression must be a boolean one, i.e. its value is either true or false for each row of the table. You can activate this dialogue using the **Add Subset** () button in the Subsets Window.

The window consists of two fields which must be filled in to define the new subset:

#### Subset Name

The name of the new subset. This should preferably be unique (different from existing subset names). It will be easier to use it in other expressions if it is also:

- Different from other columns even apart from upper/lower case distinctions
- In the form of a java identifier (starts with a letter, continues with alphanumerics including underscore)
- Not too long

#### Expression

This is a boolean expression which defines the subset; it is a function of the values of any combination of the columns; only rows for which it evaluates to true will be included in the subset. The values of the other columns in the same row are referenced using their names or \$ID identifiers, and other subsets may be referenced using their names or \_ID identifiers. The rules for expression syntax are described in Section 6, and detailed documentation of the functions you can use can be seen in the Available Functions Window, which you can see by clicking the **Show Functions** ( $f(x)$ ) button on the toolbar.

Having filled in the form to your satisfaction, hit the **OK** button at the bottom and the new subset will be added to the list that can be seen in the Subsets Window where it behaves like any other. If you have made some mistake in filling in the fields, a popup window will give you a message describing the problem.

#### A.7.10 Available Functions Window

#### Available Functions Window

This window displays all the functions (Java methods) which are available for use when writing algebraic expressions (Section 6). This includes both the built-in expressions and any extended ones

you might have added. You can find this window by using the **Show Functions** () button in the Synthetic Column or Algebraic Subset window toolbars.

On the left hand side of the window is a tree-like representation of the functions you can use. Each item in this tree is one of the following:

 **Folder**

A group of classes. There's only one of these, marked "Activation Functions", and it contains functions which are only available for use in Activation Actions (Section 7). When defining a new synthetic columns or algebraic subsets they are not used.

 **Class**

A set of functions and/or constants; it doesn't matter what class a function is in when you use it, but since the functions in a class are usually related this makes it easier to find the one you're looking for in this window.

 **Function**

A function that you can use in an expression.

 **Constant**

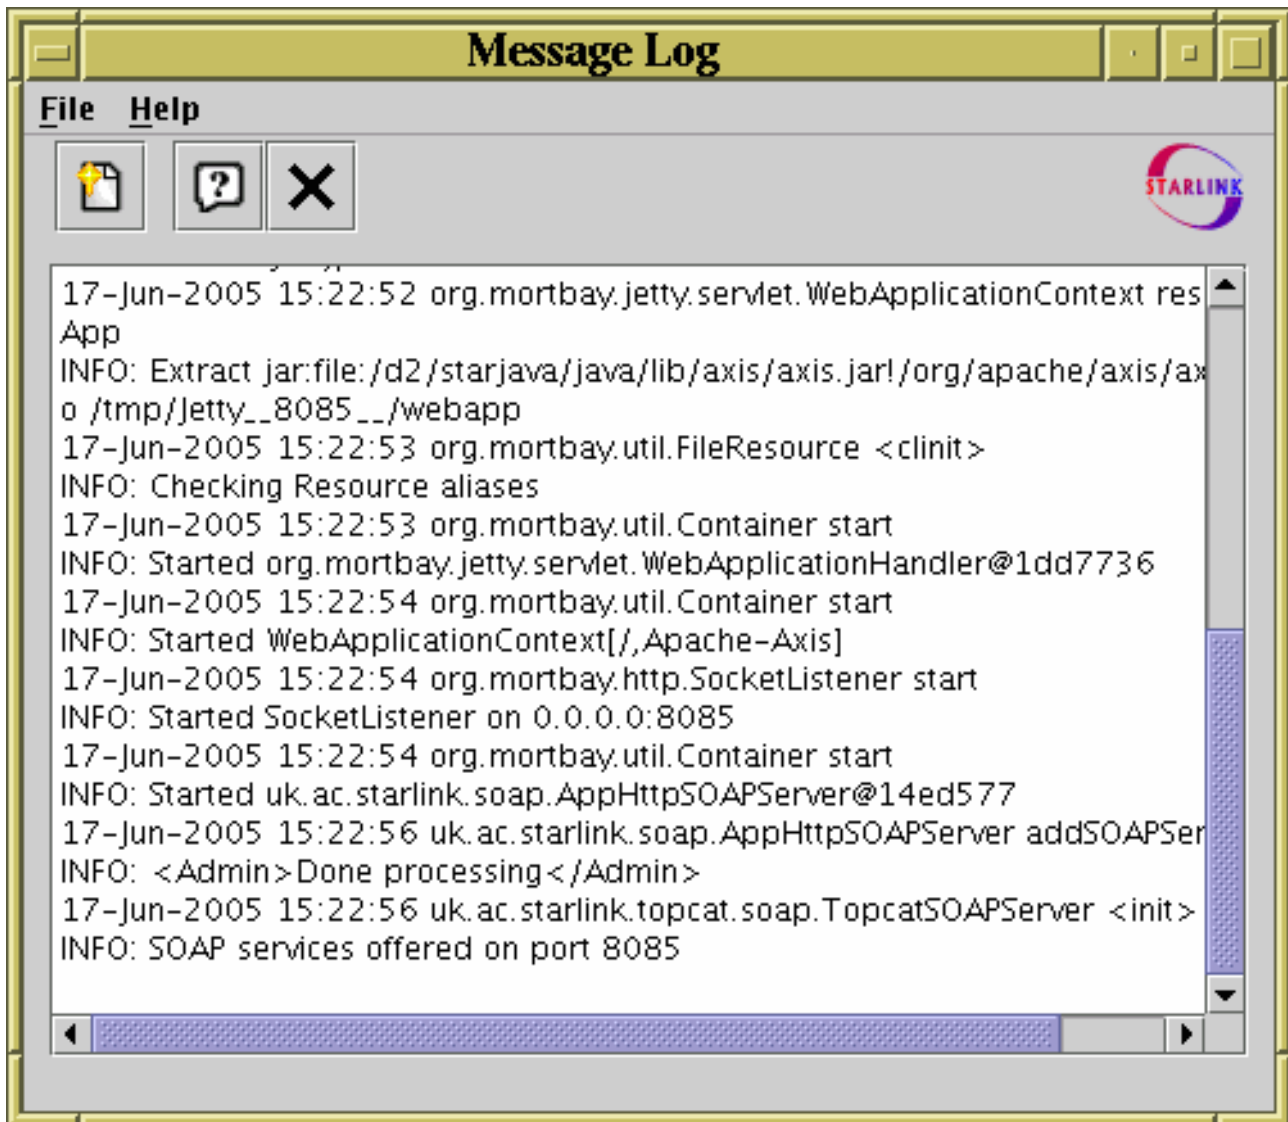

A constant value which you can refer to by name in an expression (as long as it doesn't clash with a column name).

Of these, the Folder and Class items have a 'handle' () , which means that they contain other items (classes and functions/constants respectively). By clicking on the handle (or equivalently double-clicking on the name) you can toggle whether the item is open (so you can see its contents) or closed (so you can't). So to see the functions in a class, click on its handle and they will be revealed.

You can click on any of these items and information about it will appear in the right hand panel. In the case of functions this describes the function, its arguments, what it does, and how to use it. The explanations should be fairly self-explanatory; for instance the description in the figure above indicates that you could use the invocation `atan2(X_POS, Y_POS)` as the expression for a new table column which gives the angle from the X axis of a point whose position is given by columns with the names X\_POS and Y\_POS. Examples of a number of these functions are given in Section 6.7.

Using the Add button () you can specify the name of a class to add to those available. You should enter the fully-qualified class name (i.e. including the dot-separated package path). The class that you specify must be on the class path which was current when TOPCAT was started, as explained in Section 9.2.1. Note however it would be more usual to specify these using the system property `jel.classes` or `jel.classes.activation` at startup, as described in Section 6.8. Classes added in this way will be visible in the tree, but may not have proper documentation (clicking on them may not reveal a description in the right hand panel).

### A.7.11 Log Window

## Log Window

The log window can be obtained using the **View Log** option on the **File** menu of the Control Window.

This window displays any log messages which the application has generated. Depending on whether the `-verbose` flag has been specified, some or all of these messages may have been written to console as well (if there is a console - this depends on how you have invoked TOPCAT). Under some circumstances, messages way back in the list may not be displayed.

To clear the display of all the existing messages you can use the **Clear Log** button (  ).

The messages displayed here are those written through Java's logging system - in general they are intended for debugging purposes and not for users to read, but if something unexpected is happening, or if you are filing a bug report, it may provide some clues about what's going on. Although it tries not to disturb things too much, TOPCAT's manipulation of the logging infrastructure affects how it is set up, so if you have customised your logging setup using, e.g., the `java.util.logging.config.*` system properties, you may find that it's not behaving exactly as you expected. Sorry.

## B Algebraic Functions

This appendix lists the functions which can be used in algebraic expressions (see Section 6). They are listed in two sections: the first gives the functions available for use anywhere an expression can be used, and the second gives those only for use in defining custom Activation Actions (Section 7).

Note that although all the available functions are listed here with short descriptions, their full explanation, including parameter descriptions and examples, is only available from the Available Functions Window (Appendix A.7.10), obtained using the  toolbar button.

### B.1 General Functions

The following functions can be used anywhere that you can write an algebraic expression in TOPCAT. They will typically be used for defining new synthetic columns or algebraically-defined row subsets. More complete documentation of them is available from within TOPCAT in the Available Functions Window.

#### Times

Functions for conversion of time values between various forms. The forms used are

##### Modified Julian Date (MJD)

A continuous measure in days since midnight at the start of 17 November 1858. Based on UTC.

##### ISO 8601

A string representation of the form `yyyy-mm-ddTh:mm:ss.s`, where the `T` is a literal character (a space character may be used instead). Based on UTC.

##### Julian Epoch

A continuous measure based on a Julian year of exactly 365.25 days. For approximate purposes this resembles the fractional number of years AD represented by the date. Sometimes (but not here) represented by prefixing a 'J'; J2000.0 is defined as 2000 January 1.5 in the TT timescale.

##### Besselian Epoch

A continuous measure based on a tropical year of about 365.2422 days. For approximate purposes this resembles the fractional number of years AD represented by the date. Sometimes (but not here) represented by prefixing a 'B'.

Therefore midday on the 25th of October 2004 is `2004-10-25T12:00:00` in ISO 8601 format, 53303.5 as an MJD value, 2004.81588 as a Julian Epoch and 2004.81726 as a Besselian Epoch.

Currently this implementation cannot be relied upon to better than a millisecond.

##### `isoToMjd( isoDate )`

Converts an ISO8601 date string to Modified Julian Date. The basic format of the `isoDate` argument is `yyyy-mm-ddTh:mm:ss.s`, though some deviations from this form are permitted:

- The 'T' which separates date from time can be replaced by a space
- The seconds, minutes and/or hours can be omitted
- The decimal part of the seconds can be any length, and is optional
- A 'z' (which indicates UTC) may be appended to the time

Some legal examples are therefore: "1994-12-21T14:18:23.2", "1968-01-14", and "2112-05-25 16:45Z".

**dateToMjd( year, month, day, hour, min, sec )**

Converts a calendar date and time to Modified Julian Date.

**dateToMjd( year, month, day )**

Converts a calendar date to Modified Julian Date.

**mjdToIso( mjd )**

Converts a Modified Julian Date value to an ISO 8601-format date-time string. The output format is `yyyy-mm-ddThh:mm:ss`.

**mjdToDate( mjd )**

Converts a Modified Julian Date value to an ISO 8601-format date string. The output format is `yyyy-mm-dd`.

**mjdToTime( mjd )**

Converts a Modified Julian Date value to an ISO 8601-format time-only string. The output format is `hh:mm:ss`.

**formatMjd( mjd, format )**

Converts a Modified Julian Date value to a date using a customisable date format. The format is as defined by the `java.text.SimpleDateFormat` (<http://java.sun.com/j2se/1.4.2/docs/api/java/text/SimpleDateFormat.html>) class. The default output corresponds to the string `"yyyy-MM-dd 'T' HH:mm:ss"`

**mjdToJulian( mjd )**

Converts a Modified Julian Date to Julian Epoch. For approximate purposes, the result of this routine consists of an integral part which gives the year AD and a fractional part which represents the distance through that year, so that for instance 2000.5 is approximately 1 July 2000.

**julianToMjd( julianEpoch )**

Converts a Julian Epoch to Modified Julian Date. For approximate purposes, the argument of this routine consists of an integral part which gives the year AD and a fractional part which represents the distance through that year, so that for instance 2000.5 is approximately 1 July 2000.

**mjdToBesselian( mjd )**

Converts Modified Julian Date to Besselian Epoch. For approximate purposes, the result of this routine consists of an integral part which gives the year AD and a fractional part which represents the distance through that year, so that for instance 1950.5 is approximately 1 July 1950.

**besselianToMjd( besselianEpoch )**

Converts Besselian Epoch to Modified Julian Date. For approximate purposes, the argument of this routine consists of an integral part which gives the year AD and a fractional part which represents the distance through that year, so that for instance 1950.5 is approximately 1 July 1950.

**unixMillisToMjd( unixMillis )**

Converts from milliseconds since the Unix epoch (1970-01-01T00:00:00) to a modified Julian date value

**mjdToUnixMillis( mjd )**

Converts from modified Julian date to milliseconds since the Unix epoch (1970-01-01T00:00:00).

**Strings**

String manipulation and query functions.

**concat( s1, s2 )**

Concatenates two strings. In most cases the same effect can be achieved by writing `s1+s2`,

but blank values can sometimes appear as the string "null" if you do it like that.

**concat( s1, s2, s3 )**

Concatenates three strings. In most cases the same effect can be achieved by writing `s1+s2+s3`, but blank values can sometimes appear as the string "null" if you do it like that.

**concat( s1, s2, s3, s4 )**

Concatenates four strings. In most cases the same effect can be achieved by writing `s1+s2+s3+s4`, but blank values can sometimes appear as the string "null" if you do it like that.

**equals( s1, s2 )**

Determines whether two strings are equal. Note you should use this function instead of `s1==s2`, which can (for technical reasons) return false even if the strings are the same.

**equalsIgnoreCase( s1, s2 )**

Determines whether two strings are equal apart from possible upper/lower case distinctions.

**startsWith( whole, start )**

Determines whether a string starts with a certain substring.

**endsWith( whole, end )**

Determines whether a string ends with a certain substring.

**contains( whole, sub )**

Determines whether a string contains a given substring.

**length( str )**

Returns the length of a string in characters.

**matches( str, regex )**

Tests whether a string matches a given regular expression.

**matchGroup( str, regex )**

Returns the first grouped expression matched in a string defined by a regular expression. A grouped expression is one enclosed in parentheses.

**replaceFirst( str, regex, replacement )**

Replaces the first occurrence of a regular expression in a string with a different substring value.

**replaceAll( str, regex, replacement )**

Replaces all occurrences of a regular expression in a string with a different substring value.

**substring( str, startIndex )**

Returns the last part of a given string. The substring begins with the character at the specified index and extends to the end of this string.

**substring( str, startIndex, endIndex )**

Returns a substring of a given string. The substring begins with the character at `startIndex` and continues to the character at index `endIndex-1`. Thus the length of the substring is `endIndex-startIndex`.

**toUpperCase( str )**

Returns an uppercased version of a string.

**toLowerCase( str )**

Returns an uppercased version of a string.

**trim( str )**

Trims whitespace from both ends of a string.

**padWithZeros( value, ndigit )**

Takes an integer argument and returns a string representing the same numeric value but padded with leading zeros to a specified length.

**Maths**

Standard mathematical and trigonometric functions.

**E**

Euler's number  $e$ , the base of natural logarithms.

**PI**

$Pi$ , the ratio of the circumference of a circle to its diameter.

**RANDOM**

Evaluates to a random number in the range  $0 \leq x < 1$ . This is different for each cell of the table. The quality of the randomness may not be particularly good.

**sin( theta )**

Sine of an angle.

**cos( theta )**

Cosine of an angle.

**tan( theta )**

Tangent of an angle.

**asin( x )**

Arc sine of an angle. The result is in the range of  $-pi/2$  through  $pi/2$ .

**acos( x )**

Arc cosine of an angle. The result is in the range of 0.0 through  $pi$ .

**atan( x )**

Arc tangent of an angle. The result is in the range of  $-pi/2$  through  $pi/2$ .

**exp( x )**

Euler's number  $e$  raised to a power.

**log10( x )**

Logarithm to base 10.

**ln( x )**

Natural logarithm.

**sqrt( x )**

Square root. The result is correctly rounded and positive.

**atan2( y, x )**

Converts rectangular coordinates  $(x,y)$  to polar  $(r,theta)$ . This method computes the phase  $theta$  by computing an arc tangent of  $y/x$  in the range of  $-pi$  to  $pi$ .

**pow( a, b )**

Exponentiation. The result is the value of the first argument raised to the power of the second argument.

**Formats**

Functions for formatting numeric values.

**formatDecimal( value, dp )**

Turns a floating point value into a string with a given number of decimal places.

**formatDecimal( value, format )**

Turns a floating point value into a formatted string. The `format` string is as defined by

Java's `java.text.DecimalFormat`  
 (<http://java.sun.com/j2se/1.4.2/docs/api/java/text/DecimalFormat>) class.

## Coords

Functions for angle transformations and manipulations. In particular, methods for translating between radians and HH:MM:SS.S or DDD:MM:SS.S type sexagesimal representations are provided.

### **DEGREE**

The size of one degree in radians.

### **HOUR**

The size of one hour of right ascension in radians.

### **ARC\_MINUTE**

The size of one arcminute in radians.

### **ARC\_SECOND**

The size of one arcsecond in radians.

### **radiansToDms( rad )**

Converts an angle in radians to a formatted degrees:minutes:seconds string. No fractional part of the seconds field is given.

### **radiansToDms( rad, secFig )**

Converts an angle in radians to a formatted degrees:minutes:seconds string with a given number of decimal places in the seconds field.

### **radiansToHms( rad )**

Converts an angle in radians to a formatted hours:minutes:seconds string. No fractional part of the seconds field is given.

### **radiansToHms( rad, secFig )**

Converts an angle in radians to a formatted hours:minutes:seconds string with a given number of decimal places in the seconds field.

### **dmsToRadians( dms )**

Converts a formatted degrees:minutes:seconds string to an angle in radians. Delimiters may be colon, space, characters `dm[s]`, or some others. Additional spaces and leading +/- are permitted.

### **hmsToRadians( hms )**

Converts a formatted hours:minutes:seconds string to an angle in radians. Delimiters may be colon, space, characters `hm[s]`, or some others. Additional spaces and leading +/- are permitted.

### **dmsToRadians( deg, min, sec )**

Converts degrees, minutes, seconds to an angle in radians.

In conversions of this type, one has to be careful to get the sign right in converting angles which are between 0 and -1 degrees. This routine uses the sign bit of the `deg` argument, taking care to distinguish between +0 and -0 (their internal representations are different for floating point values). It is illegal for the `min` or `sec` arguments to be negative.

### **hmsToRadians( hour, min, sec )**

Converts hours, minutes, seconds to an angle in radians.

In conversions of this type, one has to be careful to get the sign right in converting angles which are between 0 and -1 hours. This routine uses the sign bit of the `hour` argument, taking care to distinguish between +0 and -0 (their internal representations are different for floating point values).

### **skyDistance( ra1, dec1, ra2, dec2 )**

Calculates the separation (distance around a great circle) of two points on the sky.

**skyDistanceDegrees( ra1, dec1, ra2, dec2 )**

Calculates the separation (distance around a great circle) of two points on the sky in degrees.

**hoursToRadians( hours )**

Converts hours to radians.

**degreesToRadians( deg )**

Converts degrees to radians.

**radiansToDegrees( rad )**

Converts radians to degrees.

**raFK4toFK5( raFK4, decFK4 )**

Converts a B1950.0 FK4 position to J2000.0 FK5 at an epoch of B1950.0 yielding Right Ascension. This assumes zero proper motion in the FK5 frame.

**decFK4toFK5( raFK4, decFK4 )**

Converts a B1950.0 FK4 position to J2000.0 FK5 at an epoch of B1950.0 yielding Declination. This assumes zero proper motion in the FK5 frame.

**raFK5toFK4( raFK5, decFK5 )**

Converts a J2000.0 FK5 position to B1950.0 FK4 at an epoch of B1950.0 yielding Declination. This assumes zero proper motion, parallax and radial velocity in the FK5 frame.

**decFK5toFK4( raFK5, decFK5 )**

Converts a J2000.0 FK5 position to B1950.0 FK4 at an epoch of B1950.0 yielding Declination. This assumes zero proper motion, parallax and radial velocity in the FK5 frame.

**raFK4toFK5( raFK4, decFK4, bepoch )**

Converts a B1950.0 FK4 position to J2000.0 FK5 yielding Right Ascension. This assumes zero proper motion in the FK5 frame. The `bepoch` parameter is the epoch at which the position in the FK4 frame was determined.

**decFK4toFK5( raFK4, decFK4, bepoch )**

Converts a B1950.0 FK4 position to J2000.0 FK5 yielding Declination. This assumes zero proper motion in the FK5 frame. The `bepoch` parameter is the epoch at which the position in the FK4 frame was determined.

**raFK5toFK4( raFK5, decFK5, bepoch )**

Converts a J2000.0 FK5 position to B1950.0 FK4 yielding Declination. This assumes zero proper motion, parallax and radial velocity in the FK5 frame.

**decFK5toFK4( raFK5, decFK5, bepoch )**

Converts a J2000.0 FK5 position to B1950.0 FK4 yielding Declination. This assumes zero proper motion, parallax and radial velocity in the FK5 frame.

## Conversions

Functions for converting between strings and numeric values.

**toString( value )**

Turns a numeric value into a string.

**parseByte( str )**

Attempts to interpret a string as a byte (8-bit signed integer) value. If the input string can't be interpreted in this way, a blank value will result.

**parseShort( str )**

Attempts to interpret a string as a short (16-bit signed integer) value. If the input string

can't be interpreted in this way, a blank value will result.

**parseInt( str )**

Attempts to interpret a string as an int (32-bit signed integer) value. If the input string can't be interpreted in this way, a blank value will result.

**parseLong( str )**

Attempts to interpret a string as a long (64-bit signed integer) value. If the input string can't be interpreted in this way, a blank value will result.

**parseFloat( str )**

Attempts to interpret a string as a float (32-bit floating point) value. If the input string can't be interpreted in this way, a blank value will result.

**parseDouble( str )**

Attempts to interpret a string as a double (64-bit signed integer) value. If the input string can't be interpreted in this way, a blank value will result.

**toByte( value )**

Attempts to convert the numeric argument to a byte (8-bit signed integer) result. If it is out of range, a blank value will result.

**toShort( value )**

Attempts to convert the numeric argument to a short (16-bit signed integer) result. If it is out of range, a blank value will result.

**toInteger( value )**

Attempts to convert the numeric argument to an int (32-bit signed integer) result. If it is out of range, a blank value will result.

**toLong( value )**

Attempts to convert the numeric argument to a long (64-bit signed integer) result. If it is out of range, a blank value will result.

**toFloat( value )**

Attempts to convert the numeric argument to a float (32-bit floating point) result. If it is out of range, a blank value will result.

**toDouble( value )**

Converts the numeric argument to a double (64-bit signed integer) result.

**Arithmetic**

Standard arithmetic functions including things like rounding, sign manipulation, and maximum/minimum functions.

**roundUp( x )**

Rounds a value up to an integer value. Formally, returns the smallest (closest to negative infinity) integer value that is not less than the argument.

**roundDown( x )**

Rounds a value down to an integer value. Formally, returns the largest (closest to positive infinity) integer value that is not greater than the argument.

**round( x )**

Rounds a value to the nearest integer. Formally, returns the integer that is closest in value to the argument. If two integers are equally close, the result is the even one.

**roundDecimal( x, dp )**

Rounds a value to a given number of decimal places. The result is a `float` (32-bit floating point value), so this is only suitable for relatively low-precision values. It's intended for truncating the number of apparent significant figures represented by a value which you know has been obtained by combining other values of limited precision. For more control,

see the functions in the `Formats` class.

**abs( x )**

Returns the absolute value of an integer value. If the argument is not negative, the argument is returned. If the argument is negative, the negation of the argument is returned.

**abs( x )**

Returns the absolute value of a floating point value. If the argument is not negative, the argument is returned. If the argument is negative, the negation of the argument is returned.

**max( a, b )**

Returns the greater of two integer values. If the arguments have the same value, the result is that same value.

**max( a, b )**

Returns the greater of two floating point values. If the arguments have the same value, the result is that same value. If either value is blank, then the result is blank.

**min( a, b )**

Returns the smaller of two integer values. If the arguments have the same value, the result is that same value.

**min( a, b )**

Returns the smaller of two floating point values. If the arguments have the same value, the result is that same value. If either value is blank, then the result is blank.

## B.2 Activation Functions

The following functions can be used only for defining custom Activation Actions (Section 7) - they mostly deal with causing something to happen, such as popping up an image display window. They generally return a short string, which will be logged to the user to give an indication of what happened (or didn't happen, or should have happened). More complete documentation of them is available from within TOPCAT in the Available Functions Window.

### TwoQZ

Specialist functions for use with data from the the 2QZ survey. Spectral data are taken directly from the 2QZ web site at <http://www.2dfquasar.org/> (<http://www.2dfquasar.org/>).

**TWOQZ\_SPEC\_BASE**

String prepended to the object NAME for the FITS spectra file URL.

**TWOQZ\_SPEC\_TAIL**

String appended to the object NAME for the FITS spectra file URL.

**TWOQZ\_FITS\_IMAGE\_BASE**

String prepended to the object NAME for the FITS postage stamp URL.

**TWOQZ\_FITS\_IMAGE\_TAIL**

String appended to the object NAME for the FITS postage stamp URL.

**TWOQZ\_JPEG\_IMAGE\_BASE**

String prepended to the object NAME for the JPEG postage stamp URL.

**TWOQZ\_JPEG\_IMAGE\_TAIL**

String appended to the object NAME for the JPEG postage stamp URL.

**spectra2QZ( name, nobs )**

Displays all the spectra relating to a 2QZ object in an external viewer (SPLAT).

**image2QZ( name )**

Displays the postage stamp FITS image for a 2QZ object in an image viewer.

**jpeg2QZ( name )**

Displays the postage stamp JPEG image for a 2QZ object in an external viewer.

**get2qzSubdir( name )**

Returns the name of the subdirectory (such as "ra03\_04") for a given 2QZ object name (ID).

**System**

Executes commands on the local operating system. These are executed as if typed in from the shell, or command line.

**exec( cmd, arg1 )**

Executes an operating system command with one argument.

**exec( cmd, arg1, arg2 )**

Executes an operating system command with two arguments.

**exec( cmd, arg1, arg2, arg3 )**

Executes an operating system command with three arguments.

**exec( line )**

Executes a string as an operating system command. Any spaces in the string are taken to delimit words (the first word is the name of the command).

**SuperCosmos**

Specialist display functions for use with the SuperCOSMOS survey. These functions display cutout images from the various archives hosted at the SuperCOSMOS Sky Surveys (<http://www-wfau.roe.ac.uk/sss/> (<http://www-wfau.roe.ac.uk/sss/>)). In most cases these cover the whole of the southern sky.

**SSS\_BASE\_URL**

Base URL for SuperCOSMOS image cutout service.

**sssCutout( ra, dec, pixels )**

Displays a cutout image in one of the available bands from the SuperCOSMOS Sky Surveys. The displayed image is square, and `pixels` pixels in the X and Y dimensions. Pixels are approximately 0.67 arcsec square. Sky coverage is complete.

**sssCutout( ra, dec )**

Displays a cutout image of default size in one of the available bands from the SuperCOSMOS Sky Surveys. Sky coverage is complete.

**sssCutoutBlue( ra, dec, pixels )**

Displays a cutout image of default size from one of the blue-band surveys from SuperCOSMOS. Sky coverage is complete.

**sssCutoutRed( ra, dec, pixels )**

Displays a cutout image of default size from one of the red-band surveys from SuperCOSMOS. Sky coverage is complete.

**displayUkstB( ra, dec, pixels )**

Displays a cutout image taken from the SuperCOSMOS Sky Surveys UK Schmidt Telescope Bj-band survey. The displayed image is square, and `pixels` pixels in the X and Y dimensions. Pixels are approximately 0.67 arcsec square.

Sky coverage is  $-90 < \text{Dec} < +2.5$  (degrees).

**displayUkstR( ra, dec, pixels )**

Displays a cutout image taken from the SuperCOSMOS Sky Surveys UK Schmidt Telescope R-band survey. The displayed image is square, and `pixels` pixels in the X and Y dimensions. Pixels are approximately 0.67 arcsec square.

Sky coverage is  $-90 < \text{Dec} < +2.5$  (degrees).

**displayUkstI( ra, dec, pixels )**

Displays a cutout image taken from the SuperCOSMOS Sky Surveys UK Schmidt Telescope I-band survey. The displayed image is square, and `pixels` pixels in the X and Y dimensions. Pixels are approximately 0.67 arcsec square.

Sky coverage is  $-90 < \text{Dec} < +2.5$  (degrees).

**displayEsoR( ra, dec, pixels )**

Displays a cutout image taken from the SuperCOSMOS Sky Surveys ESO R-band survey. The displayed image is square, and `pixels` pixels in the X and Y dimensions. Pixels are approximately 0.67 arcsec square.

Sky coverage is  $-90 < \text{Dec} < +2.5$  (degrees).

**displayPossE( ra, dec, pixels )**

Displays a cutout image taken from the SuperCOSMOS Sky Surveys Palomar E-band survey. The displayed image is square, and `pixels` pixels in the X and Y dimensions. Pixels are approximately 0.67 arcsec square.

Sky coverage is  $-20.5 < \text{Dec} < +2.5$  (degrees).

## Splat

Functions for display of spectra in the external viewer SPLAT.

**splat( label, loc )**

Displays the resource at a given location as a spectrum in a spectrum viewer program (SPLAT). `label` may be any string which identifies the window for display, so that multiple (sets of) spectra may be displayed in different windows without getting in each others' way. `loc` should be a filename pointing to a spectrum in a format that SPLAT understands (includes FITS, NDF). In some cases, a URL can be used too.

**splat2( label, loc1, loc2 )**

Displays two spectra in the same (SPLAT) viewer. This may be useful to compare two spectra which correspond to the same table row.

**splatMulti( label, locs )**

Generic routine for displaying multiple spectra simultaneously in the same SPLAT plot.

## Spectrum

Functions for general display of spectra in a window. Display is currently done using the SPLAT program, if available (<http://www.starlink.ac.uk/splat/>). Recognised spectrum formats include 1-dimensional FITS arrays and NDF files.

**displaySpectrum( label, location )**

Displays the file at the given location in a spectrum viewer.

**displaySpectra( label, locations )**

Displays the files at the given locations in a spectrum viewer. Each file represents a single spectrum, but they will be displayed within the same viewer window.

## Sog

Functions for display of images in external viewer SOG (<http://www.starlink.ac.uk/sog/>).

**sog( label, loc )**

Displays the file at a given location as an image in a graphical (SoG) viewer. `label` may be any string which identifies the window for display, so that multiple images may be displayed in different windows without getting in each others' way. `loc` should be a filename or URL, pointing to an image in a format that SOG understands (this includes FITS, compressed FITS, and NDFs).

**Sdss**

Specialist display functions for use with the Sloane Digital Sky Server.

**SDSS\_DR2\_BASE\_URL**

Base URL for SkyServer JPEG retrieval service, DR2.

**SDSS\_BASE\_URL**

Base URL for SkyServer JPEG retrieval service.

**sdssCutout( label, ra, dec, pixels )**

Displays a colour cutout image of a specified size from the SDSS around a given sky position. The displayed image is square, a given number of (0.4arcsec) pixels on each side.

**sdssCutout( ra, dec, pixels, scale )**

Displays a colour cutout image of a specified size from the SDSS around a given sky position with pixels of a given size. Pixels are square, and their size on the sky is specified by the `scale` argument. The displayed image has `pixels` pixels along each side.

**sdssCutout( ra, dec )**

Displays a colour cutout image of a default size from the SDSS around a given sky position. The displayed image is 128 pixels square - a pixel is 0.4arcsec.

**Output**

Functions for simple logging output.

**print( str )**

Outputs a string value to the user log.

**print( num )**

Outputs a numeric value to the user log.

**Mgc**

Specialist functions for use with data from the the Millennium Galaxy Survey.

**MGC\_IMAGE\_BASE**

String prepended to `MGC_ID` for the FITS image URL.

**MGC\_IMAGE\_TAIL**

String appended to `MGC_ID` for the FITS image URL.

**imageMgc( mgc\_id )**

Displays the postage stamp FITS image for an MGC object in an image viewer.

**Image**

Functions for display of images in a window. Supported image formats include GIF, JPEG, PNG and FITS, which may be compressed. The SoG program (<http://www.starlink.ac.uk/sog/>) will be used if it is available, otherwise a no-frills image viewer will be used instead.

**displayImage( label, location )**

Displays the file at the given location in an image viewer.

## **Browsers**

Displays URLs in web browsers.

### **basicBrowser( url )**

Displays a URL in a basic HTML viewer. This is only likely to work for HTML, text or RTF data. The browser can follow hyperlinks and has simple forward/back buttons, but lacks the sophistication of a proper WWW browser application.

### **systemBrowser( url )**

Attempts to display a URL in the system's default web browser. Exactly what counts as the default web browser is system dependent, as is whether this function will work properly.

### **mozilla( url )**

Displays a URL in a Mozilla web browser. Probably only works on Unix-like operating systems, and only if Mozilla is already running.

### **firefox( url )**

Displays a URL in a Firefox web browser. Probably only works on Unix-like operating systems, and only if Firefox is already running.

### **netscape( url )**

Displays a URL in a Netscape web browser. Probably only works on Unix-like operating systems, and only if Netscape is already running.

### **mozalike( cmd, url )**

Displays a URL in a web browser from the Mozilla family; it must support flags of the type "`-remote openURL( url )`". Probably only works on Unix-like operating systems, and only if the browser is already running.

## **BasicImageDisplay**

Functions for display of graphics-format images in a no-frills viewing window (an `ImageWindow`). Supported image formats include GIF, JPEG, PNG and FITS, which may be compressed.

### **displayBasicImage( label, loc )**

Displays the file at a given location as an image in a graphical viewer. `label` may be any string which identifies the window for display, so that multiple images may be displayed in different windows without getting in each others' way. `loc` should be a filename or URL, pointing to an image in a format that this viewer understands.

## C Release Notes

This is TOPCAT, Tool for OPERations on Catalogues And Tables. It is a general purpose viewer and editor for astronomical tabular data.

**Author**

Mark Taylor (Bristol University)

**Email**

m.b.taylor@bristol.ac.uk

**WWW**

<http://www.starlink.ac.uk/topcat/>

User comments, suggestions, requests and bug reports to the above address are welcomed.

Related software products are

**STIL**

The Starlink Tables Infrastructure Library, which provides the table handling classes on which TOPCAT is based.

**STILTS**

The STIL Tool Set, which provides some command-line tools based on STIL. The intention is that this should be a non-graphical counterpart to TOPCAT, providing many of the same facilities (matching, row selection, format conversion etc) but in a form which can be incorporated into scripts, web services, etc. The current release only contains a few of these features however.

See the TOPCAT web page, <http://www.starlink.ac.uk/topcat/> for the latest news and releases.

### C.1 Acknowledgements

TOPCAT was initially (2003-2005) developed under the UK Starlink project (1980-2005, R.I.P.). From July 2005 until June 2006, it is supported by a grant from the UK's Particle Physics and Astronomy Research Council. Its author will be funded from July 2006 until (at least) June 2007 by the European VOTech project within the UK's AstroGrid, and it is expected that support and development of the software will continue over that time.

Inspiration for many of TOPCAT's features has been taken from the following pre-existing tools:

- Mirage (Bell labs)
- VOPlot (VO-India)

Apart from the excellent Java 2 Standard Edition itself, the following external libraries provide important parts of TOPCAT's functionality:

- JEL (GNU) for algebraic expression evaluation
- PixTools (Fermilab EAG) for HEALPix-based celestial sphere row matching
- HTM (Sloan Digital Sky Survey) for HTM-based celestial sphere row matching (now deprecated within TOPCAT)
- Ptpplot (Ptolemy) for axis plotting
- EPSGraphics2D (Jibble) for encapsulated postscript output
- GifEncoder (Acme) for GIF output
- IVOA FITS Package (Sloan Digital Sky Survey) for simple (non-SoG) display of FITS images
- BrowserLauncher for launching default web browser

The following users, testers and programmers have supplied useful comments (apologies for any missed out):

- Malcolm Currie (Starlink, RAL)
- David Giaretta (Starlink, RAL)
- Clive Page (Leicester)
- Clive Davenhall (Royal Observatory Edinburgh)
- Tim Jenness (JACH)
- Mike Read (ROE)
- Peter Draper (Starlink, Durham)
- Alasdair Allan (Starlink, Exeter)
- Roy Platon (RAL)
- Norman Gray (Starlink, Glasgow)
- Jonathan Irwin (Cambridge)
- Mark Allen (Strasbourg)
- Francois Ochsenein (Strasbourg)
- Mike Watson (Leicester)
- Bob Mann (Edinburgh/Strasbourg)
- Anita Richards (Jodrell Bank)
- Eduardo Gonzalez-Solares (IoA)
- Danny Boxhoorn (Kapteyn, Groningen)
- Aaron Robotham (Bristol)
- David Mills (Bristol)
- Douglas Morgan (Bristol)
- James Price (Bristol)
- Haggis Harris (Bath)

## C.2 Version History

Releases to date have been as follows:

### **Version 0.3b (4 June 2003)**

First public release

### **Version 0.4b (8 July 2003)**

- Row subset count column in subsets window.
- Fixed and improved broken Parameter window.
- Fixed output of table name and parameters.
- Output to LaTeX `tabular` environment now available.
- SQL access buttons now greyed out when no JDBC drivers are present.
- UCD selection now available from New Synthetic Column dialogue.
- Column metadata display made more logical and flexible.
- Column cardinality now calculated in Stats window.
- Synthetic column expressions and most other column metadata now editable.
- Null value support in evaluated expressions.
- Integral example data provided.
- Hierarchical browser for tables available in load dialogue.

### **Version 0.4-1b (10 July 2003)**

- Fixed a VOTable output bug (not escaping XML special characters).
- Fixed a serious FITS output bug.
- Improved bad value handling for FITS tables.

### **Version 0.5b (20 October 2003)**

- Can now read plain text format tables.
- FITS files of arbitrary size can now be read (they are not loaded into memory).
- TOPCAT can now run without errors in a secure environment (e.g. as an unsigned jar file under WebStart). Of course some actions such as Save Table are unavailable in this context.
- Files compressed with Unix `compress` now work (as well as `gzip` and `bzip2`).
- Added hierarchy browser to load dialog.
- Added integral demo data (accessible from load dialog).
- Can now drag tables from Treeview into TOPCAT load dialog (or load button).
- Some bugfixes.

#### Version 0.5-1 (18 November 2003)

- Rewrite of FITS binary table access for big efficiency improvements.
- It's now possible to plug in user-defined algebraic methods at runtime.
- Improved unit testing leads to some bugfixes.

#### Version 1.1-0 (21 April 2004)

- User interface redesigned - now based around Control Window not table browser (much easier to work with multiple tables).
- Extensive facilities for table joining by matching rows between multiple tables or within a single one.
- Documentation much improved and available on- or off-line as SUN/253.
- Self-contained table access library STIL now provided as a separate product.
- Tables can be concatenated.
- Better top-level control over window proliferation.
- Columns can now be hidden/revealed not just deleted.
- Additional output formats/variants supported:
  - VOTable using BINARY or FITS encoding, inline or by reference
  - Machine-readable plain ASCII stream
  - HTML `<TABLE>` element or document
- Hybrid DOM/SAX parsing of VOTables for improved efficiency/memory usage.
- New flag `-demo` starts up with demo data.
- Miscellaneous efficiency improvements and bug fixes.

#### Version 1.1-3 (5 May 2004)

- Functions provided for radians $\leftrightarrow$ sexagesimal conversion

#### Version 1.3 (20 October 2004)

This version has introduced many improvements in scalability, efficiency and functionality. TOPCAT is now quite happy with tables of a million rows or more (and hundreds of columns) even on systems with quite modest memory/CPU resources. The main improvements are as follows:

##### Plotting

- Plotting is much faster and can handle many more points
- Subsets can be selected from plot window by tracing out a non-rectangular region
- You have more choice over plotting symbols (including semi-transparent ones)
- Finally X or Y axes can be flipped!
- Export to encapsulated PostScript is of improved quality (though for many points file sizes can get large)
- Export to GIF format is available
- Regression lines can be plotted and coefficients displayed (experimental capability - could be improved)

### Table Formats

- "-disk" flag allows use of disk backing storage for large tables
- New 'FITS-plus' format stores rich table/column metadata in a FITS file
- VOTable handler now fully VOTable 1.1 and 1.0 compatible
- VOTable parsing now works with Java 5.0 platform
- Comma-Separated Value format now supported for input and output
- ASCII input handler rewritten to cope with much larger tables
- ASCII handler now understands d/D as exponent letter as well as e/E
- ASCII handler now uses Short/Float not Integer/Double where appropriate to save memory
- ASCII format fixed bug for -0 degrees/hours in sexagesimal angles
- Null handling improved for FITS & VOTable formats
- FITS files store column descriptions in TCOMMx headers
- Better error messages for unparsable tables

### Table Joins

- Various efficiency improvements and reductions in memory requirements
- In cases of multiple possible matches, the closest is now chosen rather than picking one at random
- Pair match now adds column containing score for each match (distance between points)
- Units can be selected RA/Dec columns and match errors (so it doesn't need to be all in radians)
- New match types suitable for multivariate matching (anisotropic Cartesian, Sky+X, Sky+XY)

### Data/Metadata Manipulation

- Can add/remove table parameters
- One-step column replacement dialogue from data or column windows
- Synthetic column expressions now written out to column descriptions

### GUI Navigation and Display

- Improved rendering of numbers in tables (esp. Floats)
- Better detection of displayed table column widths
- New Control Window option on File menus
- Better window resizing for some dialogue boxes
- Less confusing error messages in many places

### Algebraic Expressions

- All available functions are now fully documented in help document and interactive Method Window
- Many new trig, coordinate, type conversion, string manipulation functions
- Big performance improvements for null values

### Activation Actions

- Clicking a point in the plot highlights the corresponding row in the data window and vice versa
- Row selection can trigger display sky cutout region display
- Row selection can trigger user-defined actions on activation

In addition, the following incompatibilities and changes have been introduced since the last version:

- The input format for tables can now be specified in the load window (via a selection box) or on the command line (using the "-f" flag). FITS files and VOTables can still be identified automatically (i.e. it's not necessary to specify format in this case) but ASCII tables cannot: you *must* now specify the format when loading ASCII tables. This change allows better error messages and support for more text-like formats.
- Algebraic expressions referencing row subsets now use the underscore character ("\_") rather than the hash character("#") to indicate a subset ID.
- Classes containing user-supplied functions for algebraic expressions are now specified using the properties "jel.classes" and "jel.classes.activation", not "gnu.jel.static.classes".
- The default output format for FITS tables is now the so-called "FITS-plus" format, which has a BINTABLE in its first extension as before, but the text of a VOTable stored in its primary HDU. This can store more metadata for TOPCAT, but should behave just the same for other FITS-compatible applications. The old behaviour can be restored if desired by specifying "FITS-basic" format.

### Version 1.3-1 (10 November 2004)

Minor changes:

- 2MASS cutout servers now available from Activation Window
- Added Starlink logo to all windows

### Version 1.3-2 (6 Dec 2004)

Bug fix:

- Error in parsing empty VOTable TD elements fixed.

### Version 1.4 (4 Feb 2005)

#### Load Dialogues

The graphical table load dialogue has been overhauled, and now has two main new features. First, it has been rewritten so that the GUI does not freeze during a long load; it is still currently not possible to interact with other TOPCAT windows while a load is taking place, but you can now cancel a load that is in progress.

Secondly, the provision of load dialogues has been modularised, and a number of new dialogues provided. The new ones are:

- Cone Search
- MySpace Browser
- Registry Query
- SIAP Query

If the required classes are present, you can acquire tables from these external sources as well as the traditional methods of loading from disk etc. New command line flags corresponding to each of these have been added to ensure that they are present and make them prominent in the load dialogue. Furthermore it is possible to plug in additional load dialogues at runtime using the `startable.load.dialogs` system property.

The appearance of the Load Window has changed; now only the **File Browser** button is visible along with the **Location** field in the body of the window, but the **DataSources** menu can be used to display other available table import dialogues.

#### Packaging

The program can now be obtained in two standalone forms: `topcat-full.jar` and `topcat-lite.jar`. The former is much larger than before (11 Mbyte), since it contains a number of classes to support custom load dialogues such as the MySpace browser and web service interaction, as well as the SoG classes. The latter contains only the classes for the core functionality, and is much smaller (3 Mbyte).

**Explode Array Column action**

There is now a new button in the Columns Window which replaces an array-valued column with a scalar column for each of its elements.

**Paste'n'Load**

You can now load a table by pasting its filename or URL as text into the table list in the Control Window (using the X selection on X-windows - not sure if or how this works on other platforms).

**Help message**

The result of `topcat -help` is now more comprehensive, describing briefly what each option does and listing system properties as well as arguments/flags proper.

**Version 1.4-1 (8 February 2005)**

- Added Search Column item to Data Window column popup menu

**Version 1.5 (17 March 2005)****File Access**

Load dialogues have changed again somewhat, and save dialogues as well. The default file browser in both cases is now a *Filestore Browser*, which is very much like the standard file browser, but can browse files in remote filesystems as well; currently supported are files in AstroGrid's MySpace or on an SRB (Storage Resource Broker) server. You can now save files to these remote locations as well as load from them.

In addition, the save dialogue now displays the current row subset and sort order - this makes it easier to see and/or change the details of the table you're about to save.

**BugFixes**

A few more minor changes have been made.

- Error display dialogue boxes have been improved in some places
- Various bugs relating to JDBC database access have been fixed
- Some minor issues relating to VOTables with single-character columns have been addressed

**Version 1.6 (30 June 2005)****Activation Actions**

Some more activation functionality has been added:

- New **View URL as Web Page** option introduced in Activation Window
- New **System** class of activation functions containing `exec` functions which execute commands on the local operating system
- New **Browsers** class of activation functions for displaying URLs in web browsers (external or basic fallback one)

**Algebraic Functions**

New **Times** class added containing functions for converting between Modified Julian Day and ISO 8601 format epochs.

**Sky Matching**

The default sky matching algorithm now uses HEALPix rather than HTM for assigning sky pixels to RA,Dec positions. This gives much faster sky matches in most cases, and uses somewhat less memory so can be used on larger tables. It has also fixed a bug which missed out some possible matches. HTM-based matching is currently still provided as an option, but this is mainly for debugging purposes and may be withdrawn in the future.

**Logging**

The message logging has been tidied up. The main observable consequence of this is that fewer untidy messages are written to the console when TOPCAT is run from a standalone jar file rather than a full starjava installation. By specifying the new `-verbose` (or `-v`) flag one or more times you can get those messages back. The messages (in fact all logging messages at any level) can also be viewed from the GUI by using the new **File>Show Log** menu option from the Control Window.

### SOAP Services

TOPCAT now acts as a SOAP server; SOAP requests can now be made to a running instance of TOPCAT to get it to display tables by location or by sending XML for a VOTable direct. Because of limitations in Axis, this latter method won't work for arbitrarily large tables.

### Documentation changes

The `tablecopy` tool is no longer covered in this document; it is replaced by the `tcopy` tool in the separate STILTS (<http://www.starlink.ac.uk/stilts/>) package. There has also been some reorganisation of this document, mainly in the appendices.

### Minor changes

- Added `-version` flag
- Added (dummy) **Print** option to Data Window. This just presents a message to the effect that you should save to a printable format.
- Fixed a bug which gave errors when expressions contained a `NULL_` test on the first column of a table.
- Modified one of the demo tables to contain a column with URLs in it.

### Version 1.6-1 (7 July 2005)

Bugfixes:

- Work around AstroGrid/Sun bug which prevented loading short VOTables from MySpace.
- Ensure that filestore browsers are kept up to date when dialogues are displayed.

### Version 1.7 (30 September 2005)

#### Crossmatching

There have been major improvements in the flexibility, and minor improvements to performance, of two-table crossmatching.

- New match algorithm **Sky with Errors** introduced. This allows you to specify a column giving the maximum permissible match error (so it can vary per row) rather than a fixed value for the whole table.
- In the case of multiple possible matches between the two tables, instead of automatically giving you only the closest match, you can now select whether you'd like only the closest one or all those which fit your criteria.
- You can now specify which rows you want to see in the output: 1 and 2, 1 or 2, All from 1, All from 2, 1 not 2, 2 not 1, 1 xor 2. This is pretty much all the possibilities which make sense, and in particular allows you to do 'left outer joins' (1 not 2).
- The match score column which results from most matches now comes (a) in sensible units where possible (e.g. arcseconds not radians) and (b) with metadata which tells you what its meaning and units are.
- More information is available in added columns after the match; as well as the match score, information about matched groups is inserted where appropriate.
- The "Spherical Polar" match algorithm is now rebadged as the hopefully less confusing "Sky 3d".

Similar changes for 1-table and multi-table matches should follow in future versions.

**MySpace Access**

MySpace I/O has been re-implemented to use the ACR rather than the (now deprecated) CDK classes it was using before. As well as probably being more reliable and less likely to break with future changes in MySpace server protocols, this gives the benefit of single sign on. The effect of this is that you will need to have the AstroGrid desktop running on your machine before you can access MySpace from TOPCAT.

**Algebraic functions**

- Added Julian Epoch and Besselian Epoch conversion functions to `Times` class.
- Added `RANDOM` special function.

**Miscellaneous**

- When you select a column in the Columns window, it now scrolls the table in the Data Window so that the selected column is visible. This is a boon when dealing with tables that have very many columns.
- String "null" interpreted as a blank value in ASCII tables.
- Added new activation action to launch system default browser.

**Bugfixes**

- Fixed some relatively harmless bugs to do with actions available when you select the dummy "Index" column. You can now unsort from a popup menu in the table viewer window.
- Believed to work fine with Java 1.5 now (there were previously some issues with MySpace at Java 1.5).
- Fixed bug in ASCII input handler which misidentified blank lines, or DOS-format line ends, as end of file.

**Version 1.7-1 (4 October 2005)**

Bugfixes:

- Fixed broken MySpace access on MS Windows.

**Version 1.8 (13 October 2005)**

- Added **Sky Coordinates Window**; it's now easy to add new sky coordinate columns based on old ones in different coordinate systems.
- `roundDecimal` and `formatDecimal` functions introduced for more control over visual appearance of numeric values.
- Now copes with 'K'-format FITS binary table columns (64-bit integers).
- Modifications to JNLP files.

**Version 2.0 (3 February 2006)**

A major upgrade of TOPCAT's visualisation capabilities has taken place in this release. There are considerable improvements in functionality, flexibility and efficiency over previous versions:

**New graphics windows**

In addition to the 2-d scatter plot from previous versions, the following visualisation windows are now available:

- Histogram (1-d)
- 3-d Cartesian scatter plot
- 3-d Spherical scatter plot (with optional radial dimension)
- 2-d Density map (2-d histogram)

The new 3-d functionality does *not* require you to install Java3D or any other third-party 3D toolkit to work (nor does it take advantage of any such toolkit which may be present).

**Multi-dataset/multi-table plotting**

The plot windows are no longer associated with a single table. All of them allow you to display data from different tables, or from different tuples of columns of the same table, on the same plot. You can layer as many plots as you like on the same axes, using different plotting styles for the different datasets. As before, you can still display data from different subsets of the same table and same columns using different styles.

**Plotting Styles**

All the graphics windows allow you to set the plotting style for each data set individually, using a wide range of options including colour, line width, marker size, (histogram) bar style, etc. This allows you considerable control over the visual details of the plots.

**Transparent markers**

All the 2-d and 3-d scatter plots allow you to render points using markers of variable transparency. In a crowded plot, this allows you to see much more information than using opaque points, since you can get some idea of how many points (of different data sets) have been drawn at a given point on the plotting surface.

**Line drawing & linear correlation**

The 2-d scatter plot can now optionally plot lines associated with data sets. It can either draw straight line segments joining all the plotted points in a set, or draw per-dataset linear correlation lines. In the latter case it will report line gradient, intercept and correlation coefficient.

**Improved column selection**

The selector boxes for selecting which columns to plot are now 'editable' - that is, instead of selecting the column from a drop down list it is now also possible to type an expression into them instead. This may be more convenient if there is a very long list of columns. It also means that you can use an algebraic expression based on the names of one or more columns instead of a simple column name. The selectors also have small arrow boxes next to them which makes it easy to cycle through the list of known columns. These features are also available at some other places in the program where a column value is required.

**Manual axis configuration**

As well as zooming in and out using the mouse, you can now set the axis limits by typing them into an axis dialogue box. You can also set the text which will form the axis annotation on the plot.

**Status line**

Most plots now feature a panel at the bottom of the window indicating how many points have been plotted and the current position of the mouse pointer (if any) on the plotting surface.

**Performance**

Scatter plots of large datasets now use considerably less memory and around an order of magnitude less CPU time than previously (a 2-d million point replot now takes about 1 second - plotting it the first time may be rather longer since it needs to acquire the data which may be I/O intensive).

Some non graphics-related improvements have also been made as follows:

- Selection of a subset in the Control Window now triggers its selection in other windows (plot, statistics, subsets). The same thing doesn't happen the other way around, since that might lead to confusing consequences.
- Boolean columns now display null values distinctly from false ones. Additionally, null/false distinctions are handled more carefully in FITS and VOTable files.
- The Sky Coordinates Window now suggests names for new columns.
- The Filestore Browser now allows you to enter the position in a file of the table to load

- (e.g. HDU index for FITS or TABLE index for VOTable).
- Added Hide All & Reveal All actions to the Columns window.
  - When joining tables, column name comparison to determine whether deduplication is required is now case-insensitive.
  - Fixed a problem which was causing TOPCAT to crash when attempting to save an altered copy of a FITS file under the same name.
  - The manual has been reorganised somewhat, and a new Quick Start (Section 2) section added.
  - There is an experimental implementation of the Aladin interoperability interface. This hasn't really been tested however, so may not work. Improved Aladin interoperability is expected in future releases.
  - Fixed a bug in Cartesian crossmatching algorithms which failed to match if the required error in any dimension was zero.

### Version 2.1 (7 April 2006)

A number of graphical and other improvements have been made at this release.

#### Stacked Line Plot

A new Stacked Line Plot (Appendix A.4.4) visualisation window has been added. This is especially suitable for use with time series data.

#### Asynchronous data reading in graphics windows

All the graphics windows now read data for plotting asynchronously. What this means is that when you change the plot in a way which requires the data to be read or re-read then the GUI will not lock up and you can do other things, including changing the plot in other ways before it has completed drawing. A progress bar at the bottom of the window indicates progress. This is only noticeable for large (slow to read) files.

#### Axis Zooming

The existing Histogram, 2-D Scatter Plot and Density Map windows, as well as the new Stacked Line Plot, now allow you to do a 1-d zoom by dragging the mouse near the axis, as well as the 2-d zoom by dragging on the plot surface.

#### PLASTIC Tool Interoperability

TOPCAT now sends and services messages using the PPlatform for AStronomical Tool InterConnection protocol. See Section 8.

#### IPAC Data Format

Data files in the IPAC format defined by the CalTech's Infrared Processing and Analysis Center can now be read. This is how data from the Spitzer satellite amongst others is normally provided.

#### String-typed coordinate columns

If suitably identified (e.g. by UCD or units), string-valued columns which represent data in certain well-known forms, currently sexagesimal angles and ISO-8601-format dates, can now be treated directly as numeric values in column selector boxes such as the ones in the plotting windows, rather than having to define a new column using a string->numeric converter.

#### Memory Error Reporting

When the JVM runs out of memory, it now attempts to post a popup window explaining this rather than just writing a terse message to the console. This popup also gives you the opportunity to view a new section added to the documentation: Tips for Large Tables (Section 9.4).

#### SOAP Service deprecated

TOPCAT no longer by default runs a SOAP server for accepting tables. You can choose to run it by specifying the `-soap` flag on the command line. This facility may be withdrawn in future versions, in view of the fact that the PLASTIC service can provide similar functionality.

**Bug fixes and minor alterations**

- Export of GIF and Encapsulated PostScript images from the graphics windows has been improved - unwanted grey backgrounds round the edges are now rendered transparent in GIFs and white in EPS. A section on Exporting Graphics (Appendix A.4.1.4) has also been added to the manual.
- A number of graphical anomalies such as the plot bounds being reset when an axis Flip button was toggled have been ironed out.
- The JDBC behaviour has been improved: some bugs have been fixed and it now no longer asks for an SQL username/password twice.
- Work around intermittent bug when loading small files from MySpace.
- Density maps are now exported into FITS format with better WCS headers where appropriate.
- The SDSS JPEG cutout activation action URL has been updated from DR2 to DR4.
- A bug which caused the first row in a table to be included erroneously in graphical subset selections has been fixed.
- Added an offset selector toggle button to the Histogram window.
